Objectives To assess practice in the care of adults with suspected community-acquired bacterial meningitis in the

Design Retrospective cohort study.

Setting 64 UK and Irish hospitals.

Participants 1471 adults with community-acquired meningitis of any aetiology in 2017.

Results None of the audit standards, from the 2016 UK Joint Specialists Societies guideline on diagnosis and management of meningitis, were met in all cases. With respect to 20 of 30 assessed standards, clinical management provided for patients was in line with recommendations in less than 50% of cases. 45% of patients had blood cultures taken within an hour of admission. 0.5% had a lumbar puncture within 1 hour. 26% within 8 hours. 28% had bacterial molecular diagnostic tests on cerebrospinal fluid. Median time to first dose of antibiotics was 3.2 hours (IQR 1.3-9.2). 80% received empirical parenteral cephalosporins. 55% ≥60 vears and 31% of immunocompromised patients received anti-Listeria antibiotics. 21% received steroids. Of the 1471 patients, 20% had confirmed bacterial meningitis. Among those with bacterial meningitis, pneumococcal aetiology, admission to intensive care and initial Glasgow Coma Scale Score less than 14 were associated with inhospital mortality (adjusted OR (aOR) 2.08, 95% CI 0.96 to 4.48; aOR 4.28, 95% CI 1.81 to 10.1; aOR 2.90, 95% CI 1.26 to 6.71, respectively). Dexamethasone therapy was weakly associated with a reduction in mortality in both those with proven bacterial meningitis (aOR 0.57, 95% CI 0.28 to 1.17) and with pneumococcal meningitis (aOR 0.47, 95% CI 0.20 to 1.10).

Conclusion This study demonstrates that clinical care for patients with meningitis in the UK is not in line with current evidence-based national guidelines. Diagnostics and therapeutics should be targeted for quality improvement strategies. Work should be done to improve the impact of guidelines, understand why they are not followed

STRENGTHS AND LIMITATIONS OF THIS STUDY

- \Rightarrow To our knowledge, this is the largest national study of the management of meningitis in the UK published to date.
- \Rightarrow The study includes all suspected communityacquired bacterial meningitis, allowing assessment of early clinical care prior to an aetiological diagnosis being made.
- \Rightarrow The study is widely translatable and representative of practice within the UK and Ireland.
- \Rightarrow The study is limited by its retrospective design, which brings associated recall bias and some missing data.
- \Rightarrow The study may also be limited by the self-selection of the sites included.

and, once published, ensure they translate into changed practice.

INTRODUCTION

Acute bacterial meningitis is a medical emergency associated with considerable death and disability in the UK.1 Successful immunisation programmes targeting Haemophilus *influenzae* type b, *Streptococcus pneumoniae* and Neisseria meningitidis means that communityacquired bacterial meningitis, particularly in children and adolescents, is now relatively rare.² The incidence of bacterial meningitis in adults in England is estimated to be approximately 1-1.25 per 100000 population overall, exceeding 9 per 100000 in people over 70 years.²³

Early recognition of meningitis, appropriate investigation and treatment saves lives.^{4 5} It is essential that front-line clinicians, who may not encounter meningitis very often, are vigilant and have a high index of suspicion to minimise poor outcomes. To help staff who are seeing patients with suspected meningitis, the UK guidelines on the diagnosis and management of acute meningitis and meningococcal sepsis in immunocompetent adults were published in 2016.⁶ The guidelines provide readily accessible, comprehensive, evidenced-based recommendations. Previous studies show that clinical care delivered in the UK is frequently non-adherent to guidelines.^{7 8} A more recent UK study highlighted a large amount of inappropriate brain imaging prior to lumbar punctures (LPs) and long delays in performing LPs.³⁹ Inadequate use of molecular diagnostics and HIV testing have also been highlighted as areas for improvement.³ The increasing risk of multidrug resistant bacteria, an ageing population susceptible to a wider variety of bacteria (eg, Listeria monocytogenes, Escherichia coli and Klebsiella pneumoniae)² and a greater appreciation that viruses are common causes of meningitis,¹⁰¹¹ makes diagnostics essential. Reports from outside the UK have shown improvements in outcomes following guideline publication and implementation.¹² We carried out a retrospective observational study with the dual aims of (1)assessing current clinical practice regarding diagnosis and management of adult patients with suspected communityacquired bacterial meningitis and (2) to identify areas for improvement.

METHODS

Hospitals in the UK were invited to take part in this study via the National Infection Trainees Collaborative for Audit and Research network, the UK Meningitis study network, the British Infection Association and through personal contacts. Eligible patients were identified via hospital coding data, laboratory data or a combination of both. Data from patients aged 16 or over who presented with suspected acute community-acquired bacterial meningitis during 2017 were eligible for screening. Patients who met our case definition for confirmed acute meningitis, regardless of aetiology, were eligible for inclusion (box 1). Definitions are as previously published.³ Many interventions are performed prior to knowing the diagnosis, therefore, we included all meningitis in the analysis, including viral and those in whom no pathogen was identified. This allowed us to assess the entire clinical pathway of patients presenting with possible bacterial meningitis, although some would be ultimately diagnosed with a different aetiology.

Standards indicative of good practice were taken from the 2016 UK Joint Specialists Societies guideline on the diagnosis and management of meningitis and meningococcal sepsis in immunocompetent adults, and the Standards in Microbiological Investigations on the processing of cerebrospinal fluid (CSF) (B27).⁶¹³ For each standard, the number of patients as a proportion of the total cohort who received clinical care in line with the standard is

Box 1 Inclusion and exclusion criteria for cases of meningitis

A meningitis case was defined as:

- ⇒ Patients with a cerebrospinal fluid (CSF) white cell count>4×10⁶ cells/L (regardless of whether a pathogen was identified or not) and a clinical suspicion of meningitis at the time OR
- ⇒ In the case of bacterial meningitis, symptoms and signs of meningitis with a significant pathogen in the CSF (culture or PCR) or blood regardless of CSF leucocyte count

Patients with the following diagnoses were excluded:

- \Rightarrow Cryptococcal meningitis
- \Rightarrow Tuberculous meningitis
- ⇒ Nosocomial meningitis (defined as meningitis that occurs during a hospital admission or within 30 days of discharge or meningitis associated with indwelling devices in the central nervous system)
- ⇒ Encephalitis (defined as altered consciousness for >24 with no other cause found and two or more of the following signs: fever or history of fever (≥38°C) during the current illness; seizures or focal neurological signs (with evidence of brain parenchyma involvement); CSF pleocytosis (>4×10⁶ cells/L); Electroencephalogram suggesting encephalitis; and neuroimaging suggestive of encephalitis).

reported. A second adjusted analysis taking account of missing data is also reported, whereby the number of patients as a proportion of the cohort with available data who received clinical care in line with the standard was reported.

Data were collected using electronic case report forms on REDcap, a password-protected central web-based database system. All microbiological diagnostic procedures were performed at the local hospital laboratory for each participating site using locally approved procedures. All data were anonymised and recorded under a unique participant identification number.

Statistical analyses

Descriptive statistics were used to summarise data. Categorical data were summarised using counts and percentages. Denominators presented are based on available data, where incomplete case records were submitted by contributing sites. For continuous variables, means and ranges or medians and IQRs are presented depending on the distribution of the data. Categorical data were analysed using χ^2 or Fisher's exact test. Continuous data were analysed using t-tests, Mann-Whitney U or Kruskal-Wallis depending on the distribution of the data. Regression analysis was used to identify potential risk factors associated with poor outcomes.

Patient and public involvement

Although there was no direct involvement of patients and public in this study the Meningitis Research Foundation, a key advocacy group for patients are represented in the authorship of the original guidelines and will be key in the dissemination of the results and the subsequent call to improve practice. Preliminary results have been shared with the Meningitis Research Foundation and some of their members.

RESULTS

1471 patients from 64 hospitals throughout the UK and Ireland took part (see online supplemental appendix 1). The hospitals ranged in size from small district generals to large teaching hospitals. The mean number of beds was 846 (range 230-2000). The hospitals who took part in England comprised 45% of the total acute bed base in England, (42 612/94 827).¹⁴ Females accounted for 57% (n=838) and the median age was 34 years (IQR 26, 49). Confirmed viral meningitis occurred in 615 (42%) and 303 had confirmed bacterial meningitis (21%). More than one-third of patients (n=553) fulfilled the case definition (box 1) but had no confirmed microbiological diagnosis and were therefore categorised as meningitis of unknown actiology. Using the criteria proposed by Spanos *et al*,¹⁵ 56 of those without a confirmed aetiology could be assumed to have bacterial meningitis. S. pneumoniae and N. meningitidis were the most common bacterial pathogens, where a cause was found, accounting for 172 (57%) and 76 (25%) of cases, respectively. H. influenzae (serotypes unknown) was found in 14 cases. Enteroviruses were the most common viral pathogens occurring in 429 (69%) of all confirmed viral meningitis. Herpes simplex virus-2 was the second most common viral pathogen detected in 97

(16%) of viral cases. Baseline demographics and clinical characteristics are shown in table 1.

Adherence to specific standards of good practice is shown in table 2. None were adhered to 100% of the time. Two-thirds of the standards (n=20) had \leq 50% adherence.

Overall, in-hospital mortality was low $(48/1471\ (3\%))$. The mortality was higher in bacterial meningitis (28/302, 13%), and pneumococcal meningitis in particular (28/172, 16%). Mortality in viral meningitis was 0.3% (2/615) and 1.5% (8/548) in those with meningitis of unknown aetiology. Just over half (157) of those with confirmed bacterial meningitis required admission to an intensive care unit (ICU).

Use of diagnostics

A few patients, 42, did not have an LP, of whom 26 (62%) had no contraindication (as specified in the 2016 joint specialties guidelines and shown in box 2). Five had meningococcal sepsis without clinical evidence of meningitis. The remaining 37 had clinical symptoms of meningism as well as a positive blood culture (n=35, 83%) and/ or a positive blood PCR (n=16, 38%) for either *S. pneumoniae* (n=23, 55%), *N. meningitidis* (n=18, 43%) or *L. monocytogenes* (n=1, 2%).

Contraindications for immediate LP were uncommon and occurred in 299 (20%) patients. Glasgow Coma Score (GCS) \leq 12 was the most common contraindication for immediate LP reported in 143 (10%), followed by

 Adherence to audit standards*

Immediate management	Number achieved standard/total number of patients analysed	% of total	Number achieved standard/total number of patients evaluable†	% of number evaluable
1. The patient's conscious level should be documented using the Glasgow Coma Scale	1283/1471	87%	1283/1448	89%
2. Blood cultures should be taken as soon as possible and within 1 hour of arrival at hospital	326/1471‡	22%	326/767§	42%
3. LP should be performed within 1 hour of arrival at hospital provided that it is safe to do so	8/1471¶	0.5%	8/1379**	0.6%
4. Antibiotic treatment should be commenced within the first hour	207/1471††	14%	207/1083‡‡	19%
5. Patients with meningitis and meningococcal sepsis should be cared for with the input of an infection specialist such as a microbiologist or a physician with training in infectious diseases and/or microbiology	1148/1471§§	78%	1148/1464	78%
Investigations				
6. Blood culture should be sent	977/1471	66%	977/1469	67%
7. Blood pneumococcal PCR should be sent	211/1471	14%	211/1460	14%
8. Blood meningococcal PCR should be sent	232/1471	16%	232/1461	16%
9. CSF opening pressure should be documented	655/1428¶¶	46%	655/1361ª	48%
10. CSF glucose with concurrent plasma glucose should be sent	607/1428¶¶	43%	607/1415	43%
11. CSF protein should be sent	1358/1428¶¶	95%	1358/1420	96%
12. Microscopy of the CSF should take place within 2 hours of the lumbar puncture	596/1428¶¶	42%	596/1203 ^b	50%
13. CSF for pneumococcal PCR should be sent in all cases of suspected bacterial meningitis	412/1428¶¶	29%	412/1418	29%
14. CSF for meningococcal PCR should be sent in all cases of suspected bacterial meningitis	434/1428¶¶	30%	434/1418	31%
15. A swab of the posterior nasopharyngeal wall should be obtained as soon as possible, and sent for meningococcal culture, in all cases of suspected meningococcal meningitis/sepsis	54/1471	4%	54/1463°	4%
16. All patients with meningitis should have an HIV test	646/1471	44%	646/1459 ^d	44%
Treatment				
17. All patients with suspected meningitis or meningococcal sepsis should be given ceftriaxone or cefotaxime	1039/1471 ^e	71%	1039/1423 ^f	73%
18. If the patient has, within the last 6 months, been to a country where penicillin resistant pneumococci are prevalent, intravenous vancomycin 15–20 mg/kg should be added 12-hourly (or 600 mg rifampicin 12-hourly intravenous or orally) ⁹	See footnote			
19. Those aged 60 or over should receive 2 g intravenous ampicillin/amoxicillin 4-hourly in addition to a cephalosporin (1B)	55/233	24%	55/197 ^h	28%
20. Immunocompromised patients (including diabetics and those with a history of alcohol misuse) should receive 2 g intravenous ampicillin/amoxicillin 4-hourly in addition to a cephalosporin		23%	26/99 ^j	26%
21. If there is a clear history of an aphylaxis to penicillins or cephalosporins give intravenous chloramphenicol $25{\rm mg/kg}$ 6-hourly	14/37	38%	14/30 ^k	47%
22. If <i>Streptococcus pneumoniae</i> is identified continue with intravenous benzylpenicillin 2.4 g 4-hourly, 2 g ceftriaxone intravenous 12-hourly or 2 g cefotaxime intravenous 6-hourly	114/172	66%	114/145 ¹	79%
23. If number of meningitidis is identified 2 g ceftriaxone intravenous 12-hourly, 2 g cefotaxime intravenous 6-hourly or 2.4 benzylpenicillin intravenous 4-hourly may be given as an alternative	52/76	68%	52/68 ^m	76%
24. If the patient is not treated with ceftriaxone (in meningococcal disease), a single dose of 500 mg ciprofloxacin orally should also be given	0/2	0%	0/2	0%
25. If <i>Listeria monocytogenes</i> is identified Give 2 g ampicillin/amoxicillin intravenous 4-hourly and continue for at least 21 days. Cotrimoxazole 10–20 mg/kg or chloramphenicol are alternatives in cases of anaphylaxis to beta lactams	4/7	57%	4/6	67% ⁿ
26. If <i>Haemophilus influenzae</i> is identified continue 2g ceftriaxone intravenous 12-hourly or 2g cefotaxime intravenous 6-hourly for 10 days	9/14	64%	9/13	69%°
27. 10 mg dexamethasone intravenous 6-hourly should be started on admission, either shortly before or simultaneously with antibiotics	67/1471	5%	67/1435 ^p	5%
28. If pneumococcal meningitis is confirmed dexamethasone should be continued for 4 days	34/172 ^q	20%	34/158 ^r	22%

 †Excludes those where there were missing data and/or where not relevant. ‡Only 977 patients had blood cultures taken. ‡Excluding those who did not have blood cultures taken and where data were missing. ¶1428 patients had an LP. "*Excludes those who did not have an LP and where data were not available. ††82 patients had data consistent with having antibiotics prior to admission, this might be or admission to a ward, or it may represent data entry error therefore, these figures are not ‡388 patients did not receive any antibiotics at all. §§310 (21%) of patients were admitted under an infection specialist, all others received or almissing data on 67. ⁸43 had no LP, 97 missing data, 128 time of microscopy was before or at the same time a CPerformed in 15/76 (20%) of proven meningococcal cases. ⁴9 known HIV positive and 3 missing data. ⁸285 patients who were definitely given antibiotics at all. ¹⁴⁸8 patients who were definitely given antibiotics at all. ¹⁴⁸8 patients who were definitely given antibiotics at all. ¹⁴⁸8 patients who were definitely given antibiotics at all. ¹⁴⁸8 patients who were admitted under an infortion antibiotics. 0/47 had antibiotics th ¹⁵¹933 patients were age over 60 but only 207 received antibiotics. 0/47 had antibiotics to ¹⁵²33 patients were aged over 60 but only 207 received antibiotics. 0/47 had antibiotics to ¹⁵³123 patients had insufficient antibiotic data. ¹⁶⁴7 patients had insufficient antibiotic data. ¹⁷⁵8 patient had insufficient antibiotic data. ¹⁷⁶9 patient had insufficient antibiotic data. ¹⁷⁶9 patient had insufficient antibiotic data. ¹⁷⁶9 patient had insufficient antibiotic data. ¹⁷⁷9 patient had insufficient antibiotic data. ¹⁷⁸9 hatient antibiotic data. ¹⁷⁹1 patient had insufficient antibiotic data. ¹⁷⁹1 patient had insuffic	t included. onsulting advice only. s the LP. locumented to have travelled to travelled to mainland Europe 1 o cover for penicillin resistant p 8 received amoxicillin at some e given and 4 on the timing. than 4 days.	o a mainland Ei 54 (54%) had b neumococci.	uropean country within the prev een to a country with a rate of	vious 6 months.

focal neurological signs in 38 (3%). A further 70 (7%) had other indications to delay LP. Neuroimaging prior to LP happened in 1094 of 1158 patients (94%), 911 (83%) of whom had no guideline-specified indication. Neuro-imaging was performed a median of 11 hours post arrival at hospital (IQR 4–21). Median time from admission to LP was 16.5 hours (IQR 8–27). Only 6 patients had an LP within 1 hour of arrival at hospital and only 326 (26%) within 8 hours.

Median time from LP to CSF microscopy was 2 hours (IQR 1.1–3.2). Time from LP to CSF analysis was significantly quicker when performed at on-site laboratories when compared with centralised laboratory processing (median 1.65 hours (IQR 1.0–2.8) compared with 2.95 hours (IQR 2.0–3.8) p<0.001).

Box 2 Indications for neuroimaging before lumbar puncture in suspected meningitis

- $\Rightarrow\,$ Focal neurological signs
- \Rightarrow Presence of papilloedema
- $\Rightarrow\,$ Continuous or uncontrolled seizures
- \Rightarrow Glasgow Coma Score \leq 12

Fewer than one-third of patients had pneumococcal (412, 28%) and meningococcal PCR (434, 29.5%) performed on their CSF. Pneumococcal PCR was done on blood in 211 (14%) patients, and meningococcal PCR in 232 (16%). Overall, 646 patients (44%) patients had a documented HIV test. Four of these were positive—two of whom had pneumococcal meningitis, one of whom had enteroviral meningitis and one had meningitis of unknown aetiology. Nine patients were previously known to be HIV positive.

Blood cultures were taken from 66% (n=977) of patients with 45% (n=438) having them taken within 1 hour of arrival at hospital.

Treatment

Overall, 285 patients (19%) did not receive antibiotics, most of whom had either viral meningitis (163) or lymphocytic meningitis with no aetiology identified (105). The remaining 1186 patients received at least one dose of antibiotics. The median time from hospital admission to first dose of antibiotics was 3.2 hours (IQR 1.3, 9.2). Among the patients who received antibiotics the antimicrobials were commenced within an hour of arrival at hospital for approximately one-fifth of patients (207/1000). In confirmed bacterial meningitis cases, 92 patients (36%) received antibiotics within an hour of arrival.

Adherence with guideline specified empirical antibiotic regimens was good with 912 (80%) receiving a thirdgeneration cephalosporin. Data are missing on antibiotic type for 47 patients. Of the 197 patients aged 60 years and over who received antibiotics, 108 (55%) received ampicillin or amoxicillin; only 55 (28%) of those had the correct dose and dosing frequency as recommended for *L. monocytogenes* meningitis. Similarly, only 36 (31%) of the immunocompromised patients, who were aged under 60, (n=115) received any ampicillin or amoxicillin for anti-*Listeria* cover. Online supplemental table 1 shows details regarding risk factors for *Listeria*.

Only 300 patients (20%) received adjunctive steroids as recommended. Steroids were given more frequently in patient with confirmed bacterial meningitis in 150 (50%) cases. In patients with pneumococcal meningitis, 97 patients (57%) received steroids.

Clinical outcomes

On multivariate analysis, having a confirmed diagnosis of bacterial meningitis was strongly associated with in-hospital mortality. Adjusting for age and sex, confirmed bacterial meningitis was associated with 26 times the odds of in-hospital mortality compared with those with other forms of meningitis (adjusted OR (aOR) 25.9, 95% CI 5.93 to 113.0), including those with no aetiology identified.

In patients with confirmed bacterial meningitis, on univariate analyses, in-hospital mortality was associated with a positive blood culture (crude OR (cOR) 2.21, 95% CI 1.04 to 4.67); GCS \leq 13 (cOR 3.24, 95% CI 1.39 to 7.52); confirmed *S. pneumoniae* meningitis (cOR 2.37, 95% CI 1.10 to 5.11); and ICU admission (cOR 4.81, 95% CI 1.99 to 11.60). These associations remained despite multivariate adjustment for age and sex (table 3).

The analysis was also conducted using only data from those who had had an LP (online supplemental table 2). The association between a positive blood culture and mortality was lost. The association between confirmed pneumococcal aetiology and mortality was approaching statistical significance and the association of ICU admission was maintained.

On both univariate and multivariate analyses (adjusted for age and sex), in patients with confirmed bacterial meningitis, the administration of dexamethasone was associated with a reduction in in-hospital mortality (aOR 0.57, 95% CI 0.28 to 1.17, p 0.12). When this analysis was restricted to include only those with confirmed *S. pneumoniae* meningitis, those who received dexamethasone had a reduced odds of in-hospital mortality (aOR 0.47, 95% CI 0.20 to 1.10, p 0.08). Neither association reached statistical significance. This analysis was also performed including the patients assumed to have bacterial meningitis according to the Spanos criteria (online supplemental table 3).

DISCUSSION

This large national study evaluated clinical management of adults with community-acquired meningitis throughout the UK and Ireland. Current practice falls short of the recommendations in the 2016 UK guide-lines.⁶ This is a concern for all patients but is of a particular worry in bacterial meningitis. The management of bacterial meningitis is time critical.^{4 16} Delays in receiving antibiotics and having an LP, the unnecessary use of brain imaging, a lack of appropriate antibiotics in those at risk of *Listeria* and the low rate of steroid administration are areas for significant improvement.

Most patients were given antibiotics prior to LP. Even taking this into consideration, the median door to antibiotic time was over 3 hours. The optimal timing of antibiotics in bacterial meningitis is not known precisely but we do know that delays lead to increased mortality.^{4 5 16} A delay of over 3 hours has been associated with a 14-fold increase risk of death.¹⁶

Delays in obtaining CSF are associated with a reduction in pathogen detection, increased exposure to unnecessary anti-infectives, prolonged hospital stays and increased mortality.^{4 6 17} In most cases, brain imaging is not indicated in adults with suspected community-acquired meningitis;⁴ however, in our cohort, a significant number of patients had unnecessary scans. Although complications following LP are rare,^{18 19} there may be an unfounded fear of cerebral herniation following LP, even in those with no clinical features of brain shift, which is leading to excessive use of imaging.²⁰ Education programmes, along with quality improvement measures, are essential to reduce the potentially harmful overuse of neuroloimaging. Additionally, it is essential that we optimise care pathways to ensure that clinicians have the time, space and equipment required to performed LPs in a timely and safe manner.^{3 21}

CSF culture positivity rates decline substantially when LP is delayed.³¹⁷ PCR can detect bacterial DNA in CSF for several days after antibiotics have been administered. In the UK, half of meningococcal disease is diagnosed on PCR alone.²² It is alarming that PCR was used, in our cohort, as a diagnostic modality in so few patients. Meningitis-specific investigation order-sets using electronic ordering, and/or reflex laboratory testing to increase use of molecular diagnostics should be considered to reduce opportunities for missed microbiological diagnoses. There is the potential for increased use of rapid technologies that can be used on site with minimal technical skill required.²³ Having rapid tests on site has been shown to reduce bed days with significant cost-savings.²⁴ Further research evaluating rapid diagnostic tests in other types of meningitis with clinically relevant outcomes is needed. We also need to increase the offer of HIV testing in patients with meningitis, as less than half the patients had a documented HIV test. Incident HIV diagnoses were

GCS, Glasgow Coma Score.

made in our cohort among patients presenting with bacterial, viral and unknown cause meningitis.

There is good evidence that corticosteroids reduce mortality in pneumococcal meningitis with no clinically significant increase in adverse events in other causes of meningitis.²⁵ Empirical steroids should be given for all adults with suspected bacterial meningitis. In our study, we saw a reduction in mortality in patients with pneumococcal meningitis who were given steroids, while this survival benefit did not reach statistical significance, this was likely due to a type two error and the small sample of confirmed pneumococcal meningitis cases. It is of concern that well-evidenced, well-established therapies known to improve outcome, including mortality, are only being given to just over half those who might benefit. A protocolised, goal-directed bundle, including the use of corticosteroids and appropriate antibiotics, warrants evaluation in the UK. There were clear differences between centres in our study with one centre administering steroids to 26/42 (63%) of their patients and another giving them to none. It is possible that those centres that adhered to the recommendation to give steroids may also have adhered to other aspects of the guidelines more often as well, contributing to improved outcomes.

Although this is a large multinational study, there are limitations. NHS trusts self-selected themselves for inclusion, we cannot rule out any significant differences with trusts that did not. However, 64 hospitals were included with good representation throughout the nations of the UK (and Ireland). We do not think any potential selection bias limits the generalisability of our findings. We used well-established, published case definitions of meningitis to minimise information bias; however, misclassification of cases remains possible especially in the cases without a confirmed microbiological diagnosis. Our case definitions allowed us to include anyone suspected of having meningitis (of any cause) as objectively it is often difficult to differentiate between viral and bacterial meningitis at the point of initial assessment. However, it is possible that there may have been differences in presentation between those with confirmed bacterial meningitis, those with confirmed viral meningitis and those with no confirmed aetiology that meant they were managed in different ways. This study was not powered to look at the differences between all the different aetiologies. Finally, because this was a retrospective study, our analysis may have been subject to errors resulting from recall bias and missing data. A prospective national study would have been challenging to execute and it is likely that there would have been ascertainment bias in time and geography. We therefore believe that, due to the large sample size along with the use of electronic hospital coding and laboratory data to ascertain cases, the risk of recall bias is low, and our retrospective data is representative of practice within the UK.

There is a clear need to better understand the suboptimal guideline adherence reported here. Although there has been research regarding primary care practice, there has not been any evaluation of exactly where delays occur and what the barriers are to achieving good practice in secondary care.^{26 27} A small questionnaire-based study identified the inability to find correct equipment, lack of time and/or paucity of appropriately trained staff as potential barriers to performing timely LP for the investigation of neurological infections.²¹

Non-meningitis-specific research evaluating barriers and facilitators to adhering to clinical guidelines, report a lack of awareness or familiarity with the guidelines, as well as disagreement with the content may both be important.²⁸ External barriers such as equipment and staffing were also identified which agrees with the limited research that there is in neurological infections. There is observational evidence from other countries of improvements in practice and outcome following implementation of guidelines.^{12 29}

The patient journey in the UK normally starts with being admitted via an emergency department or acute medical unit where clinicians may not be as familiar with the guidelines and evidence as specialists. There is some evidence, both within meningitis and other infectious diseases that management is improved by being looked after by a specialist. There is an expert recommendation within the current UK guidelines that patients with meningitis should be looked after with input of an infection specialist.

In conclusion, this is, to our knowledge, the largest UK study of adult patients with meningitis. Awareness of practice guidelines for relatively rare acute medical conditions such as meningitis is low and this study has demonstrated that despite clear, freely accessible guidelines, clinical care is not in line with evidence-based recommendations. There is considerable room for improvement. While we recognise that guidelines do not improve practice on their own, we do recommend that the findings from this study are strongly considered in the development of the new National Institute for Clinical Excellence (NICE) guideline on meningitis currently being developed, which for the first time, will include guidance for adult patients as well as children. Given the widespread adoption of NICE endorsed guidelines and quality standards to improve the quality of clinical practice in the UK, we anticipate that a NICE guideline will improve awareness and uptake of good practice in the short term. In addition to education, which has limited impact on changing behaviour, UK hospitals should use quality improvement methods to improve management of patients with suspected meningitis. Good qualitative research to identify what the barriers to implementing the guidelines should also be done.

We suggest a national strategic improvement plan should focus on the following key areas: timely use of diagnostics; appropriate antibiotics in at risk populations and the use of adjunctive steroids. The integrated use of electronic systems to standardise optimal use of diagnostics, and management bundles may offer additional opportunities to improve outcomes. Each site that has been involved in this study has been asked to implement site-specific changes and re-evaluate for any improvements in practice.
