## ABSTRACT

**Objective:** This study aimed to assess knowledge, attitudes and practices related to neonatal jaundice among mothers in Shenzhen, China and analyse associated factors.

**Design:** A cross-sectional study.

**Setting:** This study was conducted in Shenzhen Hospital, Southern Medical University, a university-affiliated, tertiary level-A, public hospital in China. On average, 4000 mothers are discharged from this hospital after childbirth each year, most of whom have access to a mobilephone and the Internet<sup>[1]</sup>.

**Participants:** Participants were 403 healthy mothers discharged from the study hospital from April 2021 to June 2021. Participants were recruited using convenience sampling.

**Primary outcome:** Mothers' knowledge, attitudes and practices related to neonatal jaundice, modelled using binary logistic regression.

**Secondary outcomes:** Factors associated with mother's knowledge, attitudes and practices related to neonatal jaundice.

**Results:** The questionnaire was reliable (Cronbach's alpha=0.802) and valid (scale-level content validity index=0.958) and the valid response rate was 96.4%. Only 46.4% of participating mothers had good knowledge about neonatal jaundice and only 41.7% indicated they would seek information about neonatal jaundice. A binary logistic regression analysis showed good knowledge about jaundice was associated with a high education level (i.e., master's degree or above; odds ratio [OR]=5.977, 95% confidence interval [CI]: 1.994~17.916,  $P=0.001$ ), prior education on neonatal jaundice ( $OR=3.617$ , 95%CI: 1.637~7.990,  $P=0.001$ ), and male babies ( $OR=1.714$ , 95%CI: 1.122~2.167,  $P=0.013$ ). A positive attitude toward jaundice was associated with being cared for by a 'yuesao' ( $OR=1.969$ , 95%CI: 1.264~3.066,  $P=0.003$ ) and good knowledge about jaundice ( $OR=1.804$ , 95%CI: 1.194~2.726,  $P=0.005$ ). Finally, good practices related to neonatal jaundice were associated with prior education on neonatal jaundice ( $OR=2.260$ , 95%CI: 1.105~4.625,  $P=0.026$ ) and good knowledge about jaundice ( $OR=3.112$ , 95%CI: 2.040~4.749,  $P<0.001$ ).

**Conclusion:** Many mothers have poor knowledge about jaundice, especially regarding causes, danger signs, and breast milk jaundice. Maternal information seeking behaviour about neonatal jaundice needs to be improved. Medical staff should incorporate information about the causes, danger signs of jaundice and breast milk jaundice in maternal health education. It is also necessary to strengthen health education for mothers, especially those with low education and no yuesao, and provide reliable websites where mothers can obtain information about neonatal jaundice.

**Strengths and limitations of this study**

- A strength of this study was that participants were mothers with healthy infants who had been discharged from birth hospital; these mothers may be more likely to ignore the problem of jaundice.
- The investigation time was the peak period of jaundice occurrence, which aimed to avoid recall bias.
- This study was conducted in a single health facility, meaning the findings are not broadly generalisable.
- This study only focused on new mothers and did not include significant others who may have roles in care of the newborn (e.g. grandmothers, sisters or aunts).

## INTRODUCTION

Neonatal jaundice, also known as neonatal hyperbilirubinemia, refers to yellow staining of the skin or other organs caused by the accumulation of bilirubin in the body<sup>[2]</sup>. It is a common clinical problem in the neonatal period, and approximately 50%~60% of full-term infants and 80% of premature infants develop jaundice within 1 week after birth<sup>[3]</sup>. In many infants, neonatal jaundice is a benign condition. However, severe hyperbilirubinemia may cause acute bilirubin encephalopathy (ABE) or kernicterus, which may progress to nerve deafness, choreoathetoid cerebral palsy, intellectual disability and even death<sup>[4-5]</sup>. A report from China showed that from January to December 2009, 348 cases of kernicterus were recorded in 33 hospitals<sup>[6]</sup>. In addition, a worldwide survey reported that at least 480,700 newborns develop severe hyperbilirubinemia each year, with the risk for kernicterus being 13% (n=75,400) and that for death being 24% (n=114,100)<sup>[7]</sup>. Therefore, neonatal jaundice is a serious threat to the life and health of newborns, and the associated high rates of disability and mortality place heavy burdens on society and families.

Early detection and timely treatment of neonatal jaundice are key strategies to prevent ABE and kernicterus. However, neonatal jaundice generally peaks on the 5th–7th day after birth<sup>[2]</sup>, at which time most healthy full-term infants have been discharged from hospital. Therefore, most neonatal jaundice occurs at home. As the main caregivers of newborns after discharge from hospital, mothers are often the first caregivers to observe jaundice, its progression, and early signs of ABE and kernicterus and are central to achieving favourable outcomes for management of neonatal jaundice. Wennberg<sup>[8]</sup> et al reported that providing mothers with detailed information about neonatal jaundice and its risks was associated with a reduction in the incidence of ABE in Nigeria. The Stop Kernicterus in Nigeria (SKIN) consortium<sup>[9]</sup> demonstrated that a delay in care seeking, regardless of birth site, is a major contributor to ABE and kernicterus, proposed that maternal education on neonatal jaundice should be targeted as an intervention strategy. The clinical practice guidelines for neonatal jaundice from National Institute for Health and Care Excellence<sup>[10]</sup> and American Academy of Pediatrics Subcommittee<sup>[3]</sup> also recommend that parents and caregivers are educated about neonatal jaundice, especially on how to check their baby for jaundice and what to do when jaundice is suspected. These suggest that maternal jaundice instruction be given high priority

1 among the myriad topics. However, effective instruction starts with meaningful engagement between hospital staff  
2 and mothers<sup>[11]</sup>. This highlights the hospital staff need to clarify what mothers know about jaundice and their  
3 current attitudes and practices, which will allow health education programmes to target identified gaps. In China,  
4 no evaluation tools and reports related to maternal knowledge, attitudes and practices about neonatal jaundice are  
5 available.  
6  
7  
8  
9

10 Therefore, this study designed a questionnaire to assess knowledge, attitudes and practices related to neonatal  
11 jaundice among mothers in Shenzhen, China. The information obtained maybe used to assist healthcare providers  
12 in designing educational programmes to improve awareness about neonatal jaundice among mothers, which will  
13 ultimately help to prevent disability and deaths among newborns.

## 18 **METHODS**

### 19 **Study setting and design**

20 We conducted an anonymous, self-administered, cross-sectional survey involving 403 mothers in Shenzhen, China  
21 from April to June 2021. Participants were recruited using convenience sampling.  
22  
23  
24  
25

### 26 **Study population**

27 The target population was mothers who gave birth at Shenzhen Hospital, Southern Medical University, China from  
28 April to June 2021.  
29  
30  
31

### 32 **Inclusion and exclusion criteria**

33 Mothers were eligible if they were discharged from the hospital without serious illness after childbirth, and had  
34 access to a mobile phone and the Internet. Mothers were excluded if they were not the main caregiver of their  
35 newborn after being discharged from the hospital or could not complete the questionnaire by themselves.  
36 Moreover, we excluded mothers whose newborns were admitted to the neonatal intensive care unit for treatment or  
37 that died after birth.  
38  
39  
40  
41  
42  
43

### 44 **Ethical considerations**

45 Ethical clearance was obtained from the Ethical Review Committee of Shenzhen Hospital of Southern Medical  
46 University (approval number: NYSZYEC20210004). Data were collected from each participant after they  
47 received a clear explanation of the purpose and importance of this study and provided informed consent.  
48 Participating mothers were informed that participation was fully voluntary and they could withdraw from the study  
49 at any time or refuse to answer any question. They were also informed they could ask for clarification about  
50 any aspect of the study and that the study would not cause harm. Participants did not receive any monetary incentive  
51 to participate in this study. All personal information was de-identified and kept securely, and every effort was made  
52 to maintain participants' confidentiality. Furthermore, after the investigation, each mother was informed about  
53  
54  
55  
56  
57  
58  
59  
60

1 seeking healthcare from a nearby clinic immediately if any signs of jaundice were identified via mobile phone text  
2 messages.  
3

#### 4 **Data collection tools**

5 Data were collected using a questionnaire that covered baseline characteristics, knowledge, attitudes and practices  
6 regarding neonatal jaundice. These items were developed with reference to: 1) an established guideline on neonatal  
7 jaundice<sup>[10]</sup>, 2) an integrative review<sup>[12]</sup>, and 3) three services for investigating maternal knowledge, attitude and  
8 behaviour regarding neonatal jaundice<sup>[13-15]</sup>. We also consulted seven neonatologists and discussed the items among  
9 the research team. The draft questionnaire was pretested with 20 mothers to ensure the items were appropriate and  
10 clear. The final version of the questionnaire included 27 items. Sixteen items evaluated knowledge (categorical  
11 responses: 'true', 'false' and 'do not know'), seven items assessed attitude (categorical responses: 'strongly agree',  
12 'agree', 'not sure', 'disagree', 'strongly disagree'), and four items covered practices (yes/no responses).  
13  
14  
15  
16  
17  
18  
19  
20  
21  
22

#### 23 **Validity and reliability**

24 Content validity of the questionnaire was appraised quantitatively by sending the final version of the questionnaire  
25 to a group of experts including 7 specialists in the field of neonatology. On the basis of the experts' feedbacks  
26 about relevancy, the instrument S-CVI was calculated as 0.958, which was higher than the value of 0.8 that  
27 indicates adequate validity<sup>[16]</sup>.  
28  
29  
30

31 Cronbach's alpha<sup>[17]</sup> was used to check the reliability of the questionnaire, which is the most common measure of  
32 internal consistency. In this study, the Cronbach's alphas were 0.802 for the whole questionnaire, 0.789 for the  
33 knowledge dimension, 0.721 for the attitude dimension and 0.414 for the practice dimension. The Cronbach's  
34 alphas for the knowledge and attitude dimensions were higher than 0.7, which were within the acceptable  
35 recommended range. However, that for practice (0.414) was below 0.7<sup>[18]</sup>. The small number of items (four items)  
36 may explain the low alpha estimate for this dimension. To avoid the impact of a small number of items,  
37 Cronbach<sup>[19]</sup> proposed the mean inter-item correlation ( $\rho$ ) in 1951 to estimate the internal consistency for the  
38 dimensions with a small number of items. Generally, a mean inter-item correlation ( $\rho$ ) between 0.15 and 0.20  
39 indicates acceptable internal consistency<sup>[20]</sup>. In this study, the mean inter-item correlation was 0.15 for the practice  
40 dimension, which was within the acceptable range.  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51

#### 52 **Data collection procedures**

53 On the day each mother was discharged after delivery, the investigator informed them of the purpose, duration and  
54 method of the study, and obtained their phone number. About 5 days after discharge from the hospital, the  
55 investigator sent the questionnaire link, which was developed using the 'Question star' platform, to participating  
56 mothers via mobile phone and then called the participant to complete the questionnaire on the same day. In total,  
57 413 questionnaires were completed. We excluded 10 participants: three were not completed, three wrote their  
58 names instead of their age, two had missing data for age, one wrote her age as '240', and one participants gave  
59  
60

1 obviously unreasonable responses. This left 403 valid questionnaires for analysis, giving an effective recovery rate  
2 of 96.4%. Detailed data collection procedures are presented in Figure 1.  
3

#### 4 **Data processing and analysis**

5  
6 We used SPSS version 25.0 (IBM Corp., Armonk, NY) for all data analyses. Descriptive statistics were calculated  
7 for baseline characteristics and categorical variables using simple frequencies and percentages. The main outcome  
8 variables were knowledge, attitudes and practices. The knowledge score for each participant was determined by  
9 allotting a score of '1' to correct responses and '0' (zero) to incorrect and 'do not know' responses. Therefore, the  
10 maximum obtainable knowledge score was 16. A knowledge score  $\leq 10$  was considered poor knowledge, and scores  
11  $> 10$  represented good knowledge<sup>[21]</sup>. The attitude scores were obtained by assigning points to responses on the  
12 5-point Likert scale (1 point for 'strongly disagree' to 5 points for 'strongly agree'). The maximum obtainable  
13 attitude score was 35 points. An attitude score of  $\leq 28$  was considered a poor attitude and scores  $> 29$  were  
14 categorised as a good attitude<sup>[21]</sup>. Similarly, the practice score for each participant was determined by allotting a  
15 score of '1' to correct responses and '0' (zero) to incorrect responses. This gave a maximum obtainable practice  
16 score of 4. Those with a practice score of  $< 4$  were regarded as having poor practice, while a score of 4 was  
17 considered to reflect good practice<sup>[21]</sup>. Finally, the levels of knowledge, attitude and practice were coded as 0 for  
18 poor, 1 for good<sup>[21]</sup>.  
19

20  
21 Chi-square tests (bivariable analyses) were used to determine the association between the baseline and outcome  
22 variables. All variables with  $P < 0.05$  in the bivariable analysis were included in the binary logistic regression  
23 (multivariable analysis) to determine the associations between dependent (knowledge, attitudes and practices) and  
24 independent (baseline characteristics) variables. Statistical significance was represented by  $P < 0.05$  at a 95%  
25 confidence level.  
26

#### 27 **Patient and public involvement**

28 Before the formal survey, the researchers interviewed 20 mothers to determine the readability of the questionnaire,  
29 the time required and the best way to conduct the investigation.  
30

## 31 **RESULTS**

---

### 32 **Participants' baseline characteristics**

33 Of the 403 mothers included in our analyses, a majority were aged 28–32 years (48.9%) and 75.7% had a  
34 spontaneous vaginal delivery. Most mothers (80.6%) had received prior health education about jaundice, and most  
35 had not experienced their infants being treated for jaundice (previous infants: 86.1%; present infant: 72.0%).  
36  
37 Participants' baseline characteristics are presented in Table 1.  
38

### 39 **Mothers' knowledge of neonatal jaundice**

1 We found that 45.4% of participating mothers had good knowledge regarding neonatal jaundice. The rates of  
2 correct answers of the knowledge questions ranged from 29% to 96.8%. The questions that showed low rates of  
3 correct answers were: 'Cranial haematoma may cause neonatal jaundice' (29%), 'Blood test is the gold standard for  
4 diagnosing neonatal jaundice' (34.2%), 'It is abnormal for jaundice to appear within 24 hours after birth' (36.2%),  
5 'It is abnormal for jaundice to reappear after it subsides' (37%), and 'Breast milk jaundice is a benign and  
6 self-limited condition, where interruption of breast feeding is not recommended as a therapeutic intervention'  
7 (37%). Table 2 presents scores for knowledge about neonatal jaundice among participating mothers.  
8  
9  
10  
11  
12  
13  
14

### 15 **Mothers' attitudes towards neonatal jaundice**

16 The results revealed that 42.2% of participating mothers had poor attitudes towards neonatal jaundice. Over half of  
17 the participants strongly agreed that post-discharge observation was necessary and post-partum visits were needed  
18 to measure the bilirubin level (52.4% and 51.9%, respectively). However, some mothers believed that neonatal  
19 jaundice was a common physiological phenomenon that would not cause serious consequences (10.9%), and 29.2%  
20 lacked understanding that adequate feeding was conducive to resolving jaundice. Mothers' attitudes towards  
21 neonatal jaundice are presented in Table 3.  
22  
23  
24  
25  
26  
27

### 28 **Mothers' practices regarding neonatal jaundice**

29 In general, 53.1% of mothers had good practices regarding neonatal jaundice, and 96% checked their baby for  
30 jaundice after discharge. However, only 41.9% indicated they would take the initiative to learn about neonatal  
31 jaundice after discharge. Mothers' practices regarding jaundice are shown in Table 4.  
32  
33  
34  
35

### 36 **Factors associated with knowledge, attitudes and practices related to neonatal jaundice among mothers**

37 The binary logistic regression analysis revealed that good knowledge about jaundice was associated with a high  
38 level of education (master's degree or above; odds ratio [OR]=5.977, 95% confidence interval [CI]: 1.994~17.916,  
39 P=0.001), receiving prior health education on neonatal jaundice (OR=3.617, 95%CI: 1.637~7.990, P=0.001), and  
40 male babies (OR=1.714, 95%CI: 1.122~2.167, P=0.013). A positive attitude towards jaundice was associated with  
41 being cared for by a 'yuesao' (matron specialised in maternal and newborn care) (OR=1.969, 95%CI: 1.264~3.066,  
42 P=0.003) and good knowledge about jaundice (OR=1.804, 95%CI: 1.194~2.726, P=0.005). Finally, good practices  
43 related to jaundice were associated with prior health education on neonatal jaundice (OR=2.260, 95%CI:  
44 1.105~4.625, P=0.026) and good knowledge about jaundice (OR=3.112, 95%CI: 2.040~4.749, P<0.001). Factors  
45 associated with knowledge, attitudes and practices related to neonatal jaundice among mothers are shown in Table  
46  
47  
48  
49  
50  
51  
52  
53

---

## DISCUSSION

The majority (80.6%) of participants in this study had received prior health education on neonatal jaundice, which suggested that their knowledge about neonatal jaundice would be high. However, this study found that many mothers had poor knowledge regarding neonatal jaundice, and only 45.5% of participating mothers had good knowledge about neonatal jaundice. This may be because health workers were not adequately informed about neonatal jaundice, which suggested it is necessary to intensify efforts to improve knowledge about neonatal jaundice among health workers in China to provide better maternal instruction on neonatal jaundice, perhaps through in-service training on a scheduled basis.

The present study reported that many mothers had poor knowledge regarding the causes and danger signs of jaundice, and breast milk jaundice. Relatively few mothers provided correct answers to some items; for example, 'Cranial haematoma may cause neonatal jaundice' (29%), 'Blood test is the gold standard for diagnosing neonatal jaundice' (34.2%), 'It is abnormal for jaundice to appear within 24 hours after birth' (36.2%), 'It is abnormal for jaundice to reappear after it subsides' (37%), and 'Breast milk jaundice is a benign and self-limited condition, where interruption of breast feeding is not recommended as a therapeutic intervention' (37%). Poor knowledge about the causes and danger signs of jaundice may mean mothers turn to traditional treatments, which results in delays in seeking medical attention for neonatal jaundice, thereby contributing to the development of ABE and kernicterus<sup>[22]</sup>. Having poor knowledge of breast milk jaundice may also mean mothers discontinue breastfeeding after jaundice occurs; however brief, such discontinuation may jeopardise an infant's ability to return to exclusive breastfeeding, which is unnecessarily harmful to the infant and traumatic for mothers<sup>[23]</sup>. Therefore, it is recommended that medical staff incorporate information about the causes and danger signs of jaundice, and breast milk jaundice into neonatal jaundice health education programmes.

Importantly, our study highlighted that maternal information seeking behaviour related to neonatal jaundice needs to be improved. Only 41.7% of mothers in this study indicated they took the initiative to seek information about neonatal jaundice. This poor practice could be because physical and psychological changes in the postpartum period mean mothers' energy is limited. However, it could also be attributable to low health literacy. A previous study<sup>[24]</sup> reported that the lower the parents' health literacy, the less likely they were to take the initiative to obtain information about their child's health. Actively

1  
2  
3  
4  
5 understanding relevant knowledge will help to improve maternal awareness of neonatal jaundice, which  
6 will be conducive to managing neonatal jaundice after discharge from hospital. In addition, with the  
7 popularisation of the Internet and smart phones, more and more parents are using these ways to access  
8 parenting knowledge; however, they complain that they face major challenges in identifying whether the  
9 information is reliable<sup>[24, 25]</sup>. Therefore, it is recommended that when providing education about neonatal  
10 jaundice, medical staff also provide mothers with some reliable websites to facilitate the active information  
11 seeking about neonatal jaundice.  
12

13  
14 Our multivariate analysis revealed that mothers who had a male infant were more likely be  
15 knowledgeable about neonatal jaundice compared with mothers who had a female infant. This may  
16 be because male infants are more likely to manifest jaundice<sup>[26]</sup>. Having received prior education on  
17 neonatal jaundice from medical staff and a high education level were both determinants of knowledge  
18 about neonatal jaundice. This finding was consistent with the results of a study from Egypt<sup>[14]</sup> that  
19 confirmed it is necessary and effective for medical staff to provide information about jaundice to mothers,  
20 especially those with lower education levels.  
21

22  
23 Our multivariate analysis of attitudes revealed that mothers who were cared for by ‘yuesao’ were  
24 more likely to have a positive attitude toward neonatal jaundice than other mothers. Chinese  
25 tradition dictates that new mothers stay home and rest for a ‘confinement period’ of about 1 month  
26 (28–42 days) after giving birth, which is thought to facilitate recovery. Previous studies reported  
27 that being cared for by a *yuesao* during this stage can help improve the health of mothers and  
28 babies<sup>[27, 28]</sup>, reduce postpartum depression<sup>[29, 30]</sup>, and facilitate breastfeeding<sup>[31]</sup>. Therefore, hiring a  
29 *yuesao* to prepare post-partum foods and help with household and childcare tasks has become  
30 increasingly popular in many urban families. Our study showed that the mothers who were cared for by  
31 a *yuesao* were more likely to respond positively to neonatal jaundice. This may be because the *yuesao*  
32 offers a valuable resource for jaundice counselling. Therefore, it is important that institutions that train  
33 *yuesao* should cover dealing with common problems such as neonatal jaundice as well as maternal and  
34 child care skills.  
35

36  
37 Our multivariate analysis of practices related to neonatal jaundice revealed that mothers who had received  
38 prior education on neonatal jaundice from medical staff were more likely to have good practices related to

5 jaundice than other mothers. This finding was consistent with a study conducted in Nigeria<sup>[32]</sup> that showed  
6 mothers who obtained knowledge about neonatal jaundice from medical staff were significantly less likely  
7 to self-treat, and were more likely to seek medical treatment promptly. We also found that mothers with  
8 good knowledge about neonatal jaundice were more likely to have good attitudes and practices; this was  
9 consistent with the ‘KAP’ model<sup>[33]</sup>, which suggests greater knowledge is the basis for good attitudes and  
10 practices.

## 16 CONCLUSION

17  
18 Overall, mothers’ knowledge about jaundice was low, especially regarding cause, danger signs, and breast  
19 milk jaundice. Active information seeking behaviour about neonatal jaundice needs to be improved.  
20 Therefore, it is recommended that medical staff incorporate information about the causes, danger signs,  
21 and breast milk jaundice into neonatal jaundice health education programmes, and provide reliable  
22 websites for mothers to obtain information about neonatal jaundice. This study also showed that the  
23 mother’s education level was an important factor that is significantly associated with knowledge about  
24 jaundice. In addition, mothers receiving care from a *yuesao* tend to have positive attitudes toward jaundice.  
25 Enhancing jaundice-related education programmes targeting mothers with a low education level and no  
26 *yuesao* care is important.

	poor	233 (57.8)
Mother's practice level	good	214 (53.1)
	poor	183 (46.9)

**Note:** <sup>1</sup>Weight: low weight <2500 g; normal weight 2500–4000 g; high weight >4000 g. <sup>2</sup>Cranial haematoma: haematoma caused by rupture and bleeding of subperiosteal vessels in the parieto-occipital region due to birth injury. <sup>3</sup>yuesao: a maternity matron specialised in caring for mothers and newborn infants.

**Table 2. Maternal knowledge about neonatal jaundice (N=403)**

Items	Ture N (%)	False N (%)	Don't know N (%)	Correct rate N (%)
<b>Observation of neonatal jaundice</b>				
When newborns develop jaundice, their skin will turn yellow.	390 (96.8)	4 (1.0)	9 (2.2)	390 (96.8)
When newborns develop jaundice, their	344 (85.4)	12 (3.0)	47 (11.7)	344 (85.4)

face will turn yellow firstly.

When looking for jaundice, check the naked baby in bright and preferably natural light.

365 (90.6)	10 (2.5)	28 (6.9)	365 (90.6)
------------	----------	----------	------------

### Classification of neonatal jaundice

Neonatal jaundice is divided into physiological jaundice and pathological jaundice.

371 (92.1)	3 (0.7)	29 (7.2)	371 (92.1)
------------	---------	----------	------------

### Danger signs of neonatal jaundice

Palms and soles turn yellow, indicating that jaundice is severe.

265 (65.8)	29 (7.2)	109 (27.0)	265 (65.8)
------------	----------	------------	------------

It is an abnormal condition if the jaundice appears within first 24 h.

146 (36.2)	155 (38.5)	102 (25.3)	146 (36.2)
------------	------------	------------	------------

It is an abnormal condition that the jaundice reappears after it has subsided.

149 (37.0)	143 (35.5)	111 (27.5)	149 (37.0)
------------	------------	------------	------------

### Complication of neonatal jaundice

Severe jaundice may lead to brain damage.

325 (80.6)	7 (1.7)	71 (17.6)	325 (80.6)
------------	---------	-----------	------------

### Cause of neonatal jaundice

The mother's blood type is O, and the father's blood type is A, B, or AB, which may cause neonatal jaundice.

228 (56.6)	38 (9.4)	137 (34.0)	228 (56.6)
------------	----------	------------	------------

Cranial hematoma may cause neonatal jaundice.

117 (29.0)	39 (9.7)	247 (61.3)	117 (29.0)
------------	----------	------------	------------

Bowel obstruction may cause neonatal jaundice.

281 (69.7)	14 (3.5)	108 (26.8)	281 (69.7)
------------	----------	------------	------------

Broad bean disease(G6PD) may cause jaundice.

163 (40.4)	25 (6.2)	215 (53.3)	163 (40.4)
------------	----------	------------	------------

Breastfeeding may cause jaundice

200 (49.6)	109 (27.0)	94 (23.3)	200 (49.6)
------------	------------	-----------	------------

### Breast milk jaundice

Breast milk jaundice is a benign and self-limited condition, where interruption of breast feeding is not recommended as a therapeutic intervention.

149 (37.0)	135 (33.5)	119 (29.5)	149 (37.0)
------------	------------	------------	------------

### Diagnosis of neonatal jaundice

Blood test is the gold standard for diagnosing neonatal jaundice.

138 (34.2) 127 (31.5) 138 (34.2) 138 (34.2)

### Treatment of neonatal jaundice

Phototherapy is a common, effective and safe treatment method for neonatal jaundice.

367 (91.1) 3 (0.7) 33 (8.2) 367 (91.1)

**Table 3. Maternal attitudes towards neonatal jaundice (N=403)**

Items	Strongly disagree N (%)	Disagree N (%)	Not sure N (%)	Agree N (%)	Strongly agree N (%)
I think neonatal jaundice is a common physiological phenomenon and will not cause serious consequences. (-)	80 (19.1)	216 (53.6)	63 (15.6)	39 (9.7)	5 (1.2)
I think that a baby with jaundice, don't need treat which will self-recovered. (-)	151 (38.5)	201 (49.9)	43 (10.7)	6 (1.5)	2 (0.5)
I think it is very important to observe neonatal jaundice after discharged from the hospital.	5 (1.2)	0 (0.0)	6 (1.5)	181 (44.9)	211 (52.4)
I think it is necessary for post-partum visitors to assess jaundice condition.	8 (1.0)	0 (0.0)	8 (2.0)	182 (45.2)	209 (51.9)
I think a baby with suspected jaundice should go to the medical institution or the community healthcare centres to measure the bilirubin level in time.	3 (0.7)	5 (1.2)	10 (2.5)	230 (57.1)	155 (37.5)
I believe that adequate breastfeeding is good for jaundice.	5 (1.2)	29 (7.2)	84 (20.8)	196 (48.6)	89 (22.1)
I think it is necessary to learn the knowledge of neonatal jaundice.	2 (0.5)	0 (0.0)	10 (2.5)	216 (53.6)	175 (43.4)

**Note:** - represents reverse scored items.

**Table 4. Maternal practices regarding neonatal jaundice (N=403)**

Items	Yes	No
	N (%)	N (%)
I took the initiative to seek information about neonatal jaundice.	168 (41.7)	235 (58.3)
After discharge, I checked my infant for jaundice such as the color of the skin, sclerae, urine, bowel.	387 (96.0)	16 (4.0)
After discharge, I followed the doctor's instructions that take the infant to the medical institution or the community healthcare centres to measure the bilirubin level.	376 (93.3)	27 (6.7)
After discharge, I breastfed adequately.	359 (89.1)	44 (10.9)

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Reported on page number
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	Page 1: title page
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	Page 2-3
<b>Introduction</b>			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	Page 3-4
Objectives	3	State specific objectives, including any prespecified hypotheses	Page 4
<b>Methods</b>			
Study design	4	Present key elements of study design early in the paper	Page 4
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	Page 4 and Figure 1 data collection progress
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	Page 4
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	Page 6: The levels of knowledge, attitude and practice (for poor, for good)
Data sources/measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	Page 4-6
Bias	9	Describe any efforts to address potential sources of bias	Page 2-3 Strengths and limitations of this study
Study size	10	Explain how the study size was arrived at	NI: Sufficient sample size
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	Page 6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	Page 6
		(b) Describe any methods used to examine subgroups and interactions	Page 6
		(c) Explain how missing data were addressed	Page 5-6 excluded 10 participants' data
		(d) If applicable, describe analytical methods taking account of	NA

		sampling strategy	
		(e) Describe any sensitivity analyses	NA
<b>Results</b>			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	Figure 1 data collection progress
		(b) Give reasons for non-participation at each stage	Figure 1 data collection progress
		(c) Consider use of a flow diagram	Figure 1 data collection progress
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Page 6 and Table 1
		(b) Indicate number of participants with missing data for each variable of interest	NI

## ABSTRACT

**Objective:** This study aimed to assess knowledge, attitudes and practices related to neonatal jaundice among mothers in Shenzhen, China and analyse associated factors.

**Design:** A cross-sectional study.

**Setting:** This study was conducted in Shenzhen Hospital, Southern Medical University, a university-affiliated, tertiary level-A, public hospital in China. On average, 4000 mothers are discharged from this hospital after childbirth each year, most of whom can access a mobile phone and the Internet.

**Participants:** Participants were 403 mothers discharged from the study hospital within 48~72 hours after vaginal delivery or 96~120 hours after caesarean delivery between April and June 2021. Participants were recruited using convenience sampling.

**Primary outcome:** Mothers' knowledge, attitudes and practices related to neonatal jaundice, modelled using binary logistic regression.

**Secondary outcomes:** Factors associated with mothers' knowledge, attitudes and practices related to neonatal jaundice.

**Results:** The questionnaire was reliable (Cronbach's  $\alpha=0.802$ ) and valid (scale-level content validity index=0.958). The valid response rate was 96.4%. Only 46.4% of participating mothers had good knowledge about neonatal jaundice and 41.7% indicated they would seek information about neonatal jaundice. A binary logistic regression analysis showed good knowledge about jaundice was associated with a high education level (i.e., master's degree or above; odds ratio [OR]=5.977, 95% confidence interval [CI]: 1.994~17.916,  $P=0.001$ ), prior education on neonatal jaundice (OR=3.617, 95%CI: 1.637~7.990,  $P=0.001$ ), and male babies (OR=1.714, 95%CI: 1.122~2.167,  $P=0.013$ ). A positive attitude toward jaundice was associated with being cared for by a 'yuesao' (maternity matron specialised in caring for mothers and newborns) (OR=1.969, 95%CI: 1.264~3.066,  $P=0.003$ ) and good knowledge about jaundice (OR=1.804, 95%CI: 1.194~2.726,  $P=0.005$ ). Finally, good practices related to neonatal jaundice were associated with prior education on neonatal jaundice (OR=2.260, 95%CI: 1.105~4.625,  $P=0.026$ ) and good knowledge about jaundice (OR=3.112, 95%CI: 2.040~4.749,  $P<0.001$ ).

**Conclusion:** Many mothers have poor knowledge about jaundice, especially regarding causes, danger signs and breast milk jaundice. Maternal information seeking behaviour about neonatal jaundice needs to be improved. Medical staff should incorporate information about the causes/danger signs of jaundice and breast milk jaundice in maternal health education. It is also necessary to strengthen health education for mothers, especially those with low education and no yuesao, and provide reliable websites where mothers can obtain information about neonatal jaundice.

### Strengths and limitations of this study

- A strength of this study was that participants were mothers with healthy infants who had been discharged from the birth hospital; these mothers may be more likely to ignore the problem of jaundice.
- The investigation time was the peak period of jaundice occurrence, which aimed to avoid recall bias.
- Recruiting mothers and then surveying them at a later time may have prompted mothers to search for information about jaundice.
- This study focused on new mothers and did not include significant others who may have roles in care of the newborn (e.g. grandmothers, sisters or aunts).

### INTRODUCTION

Neonatal jaundice, also known as neonatal hyperbilirubinemia, refers to yellow staining of the skin or other organs caused by the accumulation of bilirubin in the body.<sup>[1]</sup> It is a common clinical problem in the neonatal period, and approximately 50%~60% of full-term infants and 80% of premature infants develop jaundice within 1 week after birth.<sup>[2]</sup> In many infants, neonatal jaundice is a benign condition. However, severe hyperbilirubinemia may cause acute bilirubin encephalopathy (ABE) or kernicterus, which may progress to nerve deafness, choreoathetoid cerebral palsy, intellectual disability and even death.<sup>[3-4]</sup> A report from China showed that from January to December 2009, 348 cases of kernicterus were recorded in 33 hospitals.<sup>[5]</sup> In addition, a worldwide survey reported that at least 480,700 newborns develop severe hyperbilirubinemia each year, with the risk for kernicterus being 13% (n=75,400) and that for death being 24% (n=114,100).<sup>[6]</sup> Therefore, neonatal jaundice is a serious threat to the life and health of newborns, and the associated high rates of disability and mortality place heavy burdens on society and families.

Early detection and timely treatment of neonatal jaundice are key strategies to prevent ABE and kernicterus. However, neonatal jaundice generally peaks on the 5th–7th day after birth,<sup>[1]</sup> at which time most healthy full-term infants have been discharged from hospital. Therefore, most neonatal jaundice occurs at home. As the main caregivers of newborns after discharge from hospital, mothers are often the first to observe jaundice, its progression, and early signs of ABE and kernicterus. They are central to achieving favourable outcomes for management of neonatal jaundice. Wennberg<sup>[7]</sup> et al. reported that providing mothers with detailed information about neonatal jaundice and its risks was associated with a reduction in the incidence of ABE in Nigeria. The Stop Kernicterus in Nigeria (SKIN) consortium<sup>[8]</sup> demonstrated that a delay in seeking care, regardless of birth site, was a major contributor to ABE and kernicterus and proposed that maternal education on neonatal jaundice should be targeted as an intervention strategy. The clinical practice guidelines for neonatal jaundice from the National Institute for Health and Care Excellence<sup>[9]</sup> and American Academy of Pediatrics Subcommittee<sup>[2]</sup> also recommend

1 parents and caregivers are educated about neonatal jaundice, especially on how to check their baby for jaundice and  
2 what to do when jaundice is suspected. These guidelines suggest that maternal jaundice instruction be given high  
3 priority among the myriad topics. However, effective instruction starts with meaningful engagement between  
4 hospital staff and mothers.<sup>[10]</sup> Hospital staff therefore need to clarify what mothers know about jaundice and their  
5 current attitudes and practices, which will allow health education programmes to target identified gaps. Although  
6 similar investigations have been done in other countries or regions including Ghana,<sup>[11]</sup> Accra,<sup>[12]</sup> and Egypt,<sup>[13]</sup> no  
7 evaluation tools or reports related to maternal knowledge, attitudes and practices about neonatal jaundice are  
8 available in China.

9 Therefore, this study designed a questionnaire to assess knowledge, attitudes and practices related to neonatal  
10 jaundice among mothers in Shenzhen, China. The information obtained maybe used to assist healthcare providers  
11 in designing educational programmes to improve awareness about neonatal jaundice among mothers, which will  
12 ultimately help to prevent disability and deaths among newborns.

## 13 **METHODS**

### 14 **Study setting and design**

15 We conducted an anonymous, self-administered, cross-sectional survey involving 403 mothers in Shenzhen, China  
16 from April to June 2021. Participants were recruited using convenience sampling.

### 17 **Study population**

18 The target population was mothers who gave birth at Shenzhen Hospital, Southern Medical University, China from  
19 April to June 2021.

### 20 **Inclusion and exclusion criteria**

21 Mothers were eligible for this study if they were discharged from the hospital without serious illness after  
22 childbirth and had access to a mobile phone and the Internet. Mothers were excluded if they were not the main  
23 caregiver of their newborn after being discharged from hospital or could not complete the questionnaire by  
24 themselves. Moreover, we excluded mothers whose newborns were admitted to the neonatal intensive care unit for  
25 treatment or that died after birth.

### 26 **Ethical considerations**

27 Ethical clearance was obtained from the Ethical Review Committee of Shenzhen Hospital of Southern Medical  
28 University (approval number: NYSZYEC20210004). Data were collected from each participant after they  
29 received a clear explanation of the purpose and importance of this study and provided informed consent.  
30 Participating mothers were informed that participation was voluntary, and they could withdraw from the study at  
31 any time or refuse to answer any question. They were also informed they could ask for clarification about any

1 aspect of the study and that the study would not cause harm. Participants did not receive any monetary incentive to  
2 participate in this study. All personal information was de-identified and kept securely, and every effort was made to  
3 maintain participants' confidentiality. Furthermore, after the investigation, each mother was informed via mobile  
4 phone text messages about seeking healthcare from a nearby clinic immediately if any signs of jaundice were  
5 identified.  
6  
7  
8  
9

### 10 **Data collection tools**

11 Data were collected using a questionnaire that covered baseline characteristics, knowledge, attitudes and practices  
12 regarding neonatal jaundice. These items were developed with reference to: 1) an established guideline on neonatal  
13 jaundice,<sup>[9]</sup> 2) an integrative review,<sup>[14]</sup> and 3) three services for investigating maternal knowledge, attitude and  
14 behaviour regarding neonatal jaundice.<sup>[13, 15, 16]</sup> We also consulted seven neonatologists and discussed the items  
15 among the research team. Following the review by the expert panel, nine mothers whose babies had experienced  
16 neonatal jaundice were conveniently recruited to provide input on the importance and clarity of the questionnaire  
17 items. Mothers were asked to suggest alternative wording for existing items and identify items that required  
18 deletion and addition as necessary. Some items were modified based on this review. For example, we modified  
19 'Have you ever learned about neonatal jaundice' to 'Prior health education on neonatal jaundice', 'G6PD  
20 deficiency' to 'Broad bean disease', and 'Serum total bilirubin is the gold standard for diagnosing neonatal  
21 jaundice' to 'Blood test is the gold standard for diagnosing neonatal jaundice'. No items were identified for  
22 deletion or addition. The draft questionnaire was then pretested with 20 mothers who were conveniently selected  
23 from the same hospital based on the study inclusion criteria and exclusion criteria. The final version of the  
24 questionnaire included 27 items. Sixteen items evaluated knowledge (categorical responses: 'true', 'false', 'do not  
25 know'), seven items assessed attitude (categorical responses: 'strongly agree', 'agree', 'not sure', 'disagree',  
26 'strongly disagree'), and four items covered practices (yes/no responses).

41  
42  
43

### 44 **Validity and reliability**

45 The content validity of the questionnaire was appraised quantitatively by sending the final version of the  
46 questionnaire to a group of experts including seven specialists in the field of neonatology. Based on the experts'  
47 feedback about relevance, the instrument's scale-level content validity index was calculated as 0.958, which was  
48 higher than the value of 0.8 that indicates adequate validity.<sup>[17]</sup>  
49

50 Cronbach's alpha<sup>[18]</sup> was used to check the reliability of the questionnaire, which is the most common measure of  
51 internal consistency. In this study, the Cronbach's alphas were 0.802 for the whole questionnaire, 0.789 for the  
52 knowledge dimension, 0.721 for the attitude dimension and 0.414 for the practice dimension. The Cronbach's  
53 alphas for the knowledge and attitude dimensions were higher than 0.7, and were within the acceptable  
54  
55  
56  
57  
58  
59  
60

recommended range. However, that for practice (0.414) was below 0.7.<sup>[19]</sup> The small number of items (four items) on that dimension may explain the low alpha estimate. To avoid the impact of a small number of items, Cronbach<sup>[20]</sup> proposed the mean inter-item correlation ( $\rho$ ) in 1951 to estimate the internal consistency of dimensions with a small number of items. Generally, a mean inter-item correlation ( $\rho$ ) between 0.15 and 0.20 indicates acceptable internal consistency. <sup>[21]</sup> In this study, the mean inter-item correlation was 0.15 for the practice dimension, which was within the acceptable range.

### Data collection procedure

On the day each mother was discharged after delivery, the investigator informed them of the purpose, duration and method of this study, and obtained their phone number. About 5 days after discharge from hospital, the investigator sent the questionnaire link, which was developed using the 'Question star' platform, to participating mothers via mobile phone and then called the participant to complete the questionnaire on the same day. In total, 413 questionnaires were completed. We excluded 10 participants: three did not complete the questionnaire, three wrote their names instead of their age, two had missing data for age, one wrote her age as '240' and one participant chose the first option for each question. This left 403 valid questionnaires for analysis, giving an effective recovery rate of 96.4%. Detailed data collection procedures are presented in Figure 1.

### Data processing and analysis

We used SPSS version 25.0 (IBM Corp., Armonk, NY) for all data analyses. Descriptive statistics were calculated for baseline characteristics and categorical variables using simple frequencies and percentages. The main outcome variables were knowledge, attitudes and practices. The knowledge score for each participant was determined by allotting a score of '1' to correct responses and '0' (zero) to incorrect and 'do not know' responses. Therefore, the maximum obtainable knowledge score was 16. A knowledge score  $\leq 10$  was considered poor knowledge, and scores  $> 10$  represented good knowledge.<sup>[22]</sup> The attitude scores were obtained by assigning points to responses on the 5-point Likert scale (1 point for 'strongly disagree' to 5 points for 'strongly agree'). The maximum obtainable attitude score was 35 points. An attitude score  $\leq 28$  was considered a poor attitude and scores  $> 29$  were categorised as good attitudes.<sup>[22]</sup> Similarly, the practice score for each participant was determined by allotting a score of '1' to correct responses and '0' (zero) to incorrect responses. This gave a maximum obtainable practice score of 4. Those with a practice score  $< 4$  were regarded as having poor practice, whereas a score of 4 was considered to reflect good practice.<sup>[22]</sup> Finally, the levels of knowledge, attitude and practice were coded as 0 for poor, 1 for good.<sup>[22]</sup>

Chi-square tests (bivariable analyses) were used to determine the associations between the baseline and outcome variables. All variables with  $P < 0.05$  in the bivariable analysis were included in the binary logistic regression (multivariable analysis) to determine the associations between dependent (knowledge, attitudes and practices) and

1 independent (baseline characteristics) variables. Statistical significance was represented by  $P < 0.05$  at a 95%  
2 confidence level.  
3

#### 4 **Patient and public involvement**

5 Before the formal survey, the researchers interviewed 20 mothers to determine the readability of the questionnaire,  
6  
7 the time required and the best way to conduct the investigation.  
8  
9

## 10 **RESULTS**

---

### 11 **Participants' baseline characteristics**

12  
13  
14 Of the 403 mothers included in our analyses, a majority were aged 28–32 years (48.9%) and 75.7% had a  
15 spontaneous vaginal delivery. Most mothers (80.6%) had received prior health education about jaundice from  
16 health workers on the day of normal discharge from the delivery hospital (48–72 hours after vaginal delivery or  
17 96–120 hours after caesarean delivery). Among the 403 participating mothers, 113 (28%) reported their current  
18 child was admitted to the hospital for treatment due to jaundice after discharge, and 56 (13.9%) had a previous  
19 child with a history of neonatal jaundice. Participants' baseline characteristics are presented in Table 1.  
20  
21  
22  
23  
24  
25  
26  
27

### 28 **Mothers' knowledge of neonatal jaundice**

29 We found that 45.4% of participating mothers had good knowledge regarding neonatal jaundice. The rates of  
30 correct answers to the knowledge questions ranged from 29% to 96.8%. Questions that showed low rates of correct  
31 answers were: 'Cranial haematoma may cause neonatal jaundice' (29%), 'Blood test is the gold standard for  
32 diagnosing neonatal jaundice' (34.2%), 'It is abnormal for jaundice to appear within 24 hours after birth' (36.2%),  
33 'It is abnormal for jaundice to reappear after it subsides' (37%), and 'Breast milk jaundice is a benign and  
34 self-limited condition, and interruption of breast feeding is not recommended as a therapeutic intervention' (37%).  
35  
36  
37  
38  
39  
40  
41 Table 2 presents scores for knowledge about neonatal jaundice among participating mothers.  
42

### 43 **Mothers' attitudes towards neonatal jaundice**

44  
45 The results revealed that 42.2% of participating mothers had poor attitudes towards neonatal jaundice. Over half of  
46 the participants strongly agreed that post-discharge observation was necessary and post-partum visits were needed  
47 to measure the bilirubin level (52.4% and 51.9%, respectively). However, some mothers believed that neonatal  
48 jaundice was a common physiological phenomenon that would not cause serious consequences (10.9%), and 29.2%  
49 lacked understanding that adequate feeding was conducive to resolving jaundice. Mothers' attitudes towards  
50 neonatal jaundice are presented in Table 3.  
51  
52  
53  
54  
55

### 56 **Mothers' practices regarding neonatal jaundice**

57  
58 In general, 53.1% of mothers had good practices regarding neonatal jaundice, and 96% checked their baby for  
59  
60

1 jaundice after discharge. However, only 41.9% indicated they would take the initiative to learn about neonatal  
2 jaundice after discharge. Mothers' practices regarding jaundice are shown in Table 4.

### 3 **Factors associated with knowledge, attitudes and practices related to neonatal jaundice among mothers**

4  
5  
6  
7 The binary logistic regression analysis revealed that good knowledge about jaundice was associated with a high  
8 level of education (master's degree or above; odds ratio [OR]=5.977, 95% confidence interval [CI]: 1.994~17.916,  
9  $P=0.001$ ), receiving prior health education on neonatal jaundice (OR=3.617, 95%CI: 1.637~7.990,  $P=0.001$ ), and  
10 male babies (OR=1.714, 95%CI: 1.122~2.167,  $P=0.013$ ). A positive attitude towards jaundice was associated with  
11 being cared for by a 'yuesao' (matron specialised in maternal and newborn care) (OR=1.969, 95%CI: 1.264~3.066,  
12  $P=0.003$ ) and good knowledge about jaundice (OR=1.804, 95%CI: 1.194~2.726,  $P=0.005$ ). Finally, good practices  
13 related to jaundice were associated with prior health education on neonatal jaundice (OR=2.260, 95%CI:  
14 1.105~4.625,  $P=0.026$ ) and good knowledge about jaundice (OR=3.112, 95%CI: 2.040~4.749,  $P<0.001$ ). The  
15 results of chi-square tests (bivariable analyses) for maternal knowledge, attitudes and practices related to neonatal  
16 jaundice are shown in supplementary table 1. Factors associated with knowledge, attitudes and practices related to  
17 neonatal jaundice among mothers are shown in Table 5.

---

## DISCUSSION

In this study, 45.4% of mothers had good knowledge about neonatal jaundice. This knowledge level was better than that reported in other countries such as Nepal<sup>[23]</sup> (22%), Egypt <sup>[24]</sup> (30%) and Karbala city, Iraq<sup>[25]</sup> (34%). This may be attributed to the high proportion (83.1%) of our respondents who had graduated from university. Our study also found that education level was significantly associated with knowledge about neonatal jaundice, which was consistent with the results of an earlier review.<sup>[26]</sup> Due to differences in scoring algorithms or items investigating attitudes and practices<sup>[23-25]</sup>, it was difficult to compare attitudes and behaviours reported in our study with those from other countries.

The majority (80.6%) of participants in this study had received prior health education on neonatal jaundice, which suggested that their knowledge about neonatal jaundice would be high. However, this study found that many mothers had poor knowledge regarding neonatal jaundice, with only 45.5% of participating mothers had good knowledge about neonatal jaundice. This large gap may be attributable to the gap of nearly a week between the time they received health education and the time of our investigation; some mothers might have forgotten the content of the health education. In addition, medical staff only provided post-discharge monitoring and follow-up instruction and did not include neonatal jaundice knowledge related to the questionnaire when conducting health education. Another factor that might have contributed to the comparative ineffectiveness of postnatal instruction was that the unique environment was absent that mothers received health education about jaundice from health workers in a single setting, which combined a lecture, demonstration and interactive discussion, as there is generally a rush to discharge mothers from birthing centres.

The present study reported that many mothers had poor knowledge regarding the causes and danger signs of jaundice. Relatively few mothers provided correct answers to some items; for example, 'Cranial haematoma may cause neonatal jaundice' (29%), 'Blood test is the gold standard for diagnosing neonatal jaundice' (34.2%), 'It is abnormal for jaundice to appear within 24 hours after birth' (36.2%), and 'It is abnormal for jaundice to reappear after it subsides' (37%). Poor knowledge about the causes and danger signs of jaundice may mean mothers turn to traditional treatments, which results in delays in seeking medical attention for neonatal jaundice, thereby contributing to the development of ABE and kernicterus.<sup>[11]</sup> Therefore, it is recommended that medical staff incorporate information about the causes

1  
2  
3  
4  
5 and danger signs of jaundice into neonatal jaundice health education programmes. For breast milk  
6 jaundice, this involves monitoring the jaundice without changing in the infant's breastfeeding,<sup>[27]</sup>  
7 however, 73% of mothers in this study did not know that breast milk jaundice is generally a benign  
8 condition, where interruption of breast feeding is not recommended as a therapeutic intervention. Having  
9 poor knowledge of breast milk jaundice may mean mothers discontinue breastfeeding after jaundice occurs.  
10 However brief, such discontinuation may jeopardise an infant's ability to return to exclusive breastfeeding,  
11 which is unnecessarily harmful to the infant and traumatic for mothers.<sup>[28]</sup> This means mothers of affected  
12 infants should be educated about breast milk jaundice and informed that breastfeeding should be  
13 interrupted in rare instances (i.e. if the neonate displays signs of ABE). In addition, the incidence of G6PD  
14 deficiency is high in Shenzhen.<sup>[29-30]</sup> Traditional Chinese medicine is widely used in China to prevent or  
15 treat neonatal jaundice.<sup>[31-32]</sup> However, neonates with G6PD deficiency that use such remedies may have  
16 severe jaundice.<sup>[33]</sup> Our findings suggested that most mothers (59.5%) did not know the G6PD deficiency  
17 may cause jaundice. Therefore, mothers whose neonates have G6PD deficiency should be educated about  
18 avoiding using traditional Chinese medicine to treat or prevent neonatal jaundice.

19

32 Importantly, our study highlighted that maternal information seeking behaviour related to neonatal  
33 jaundice needs to be improved. Only 41.7% of mothers in this study indicated they took the initiative to  
34 seek information about neonatal jaundice. This poor practice could be because physical and psychological  
35 changes in the postpartum period mean mothers' energy is limited. However, it could also be attributable  
36 to health literacy, which has an impact on people's health information seeking behaviour.<sup>[34]</sup> A previous  
37 study<sup>[34]</sup> reported that the lower the parents' health literacy, the less likely they were to take the initiative  
38 to obtain information about their child's health. Actively understanding relevant knowledge will help to  
39 improve maternal awareness of neonatal jaundice, which will be conducive to managing neonatal jaundice  
40 after discharge from hospital. In addition, with the popularisation of the Internet and smart phones, more  
41 parents are using these ways to access parenting knowledge. However, they complain that they face major  
42 challenges in identifying whether the information is reliable.<sup>[35-36]</sup> Therefore, it is recommended that when  
43 providing education about neonatal jaundice, medical staff also provide mothers with some reliable  
44 websites to facilitate the active information seeking about neonatal jaundice.

2  
3  
4  
5 knowledgeable about neonatal jaundice compared with mothers who had a female infant. Health  
6 workers generally perform routine jaundice evaluation during birth hospitalisation, and male sex is a  
7 risk factor for neonatal jaundice.<sup>[37]</sup> We speculated that mothers who gave birth to male infants had more  
8 opportunities to receive information about neonatal jaundice. Having received prior education on neonatal  
9 jaundice from medical staff and a high education level were both determinants of knowledge about  
10 neonatal jaundice. This finding was consistent with the results of a study from Egypt<sup>[13]</sup> that found mothers  
11 who were university graduates had the highest knowledge scores. This suggested it is necessary for  
12 medical staff to provide information about jaundice to mothers with lower education levels.

13  
14  
15  
16  
17  
18  
19  
20  
21 Our multivariate analysis of attitudes revealed that mothers who were cared for by a *yuesao* were  
22 more likely to have positive attitudes toward neonatal jaundice than other mothers. Chinese  
23 tradition dictates that new mothers stay home and rest for a ‘confinement period’ of about 1 month  
24 (28–42 days) after giving birth, which is thought to facilitate recovery. Previous studies reported  
25 that being cared for by a *yuesao* during this stage can help improve the health of mothers and  
26 babies,<sup>[38-39]</sup> reduce postpartum depression,<sup>[40-41]</sup> and facilitate breastfeeding.<sup>[42]</sup> Therefore, hiring a  
27 *yuesao* to prepare post-partum foods and help with household and childcare tasks has become  
28 increasingly popular in many urban families. Our study showed that mothers who were cared for by a  
29 *yuesao* were more likely to respond positively to neonatal jaundice. This may be because the *yuesao*  
30 offers a valuable resource for jaundice counselling. Therefore, it is important that institutions that train  
31 *yuesao* should cover dealing with common problems such as neonatal jaundice as well as maternal and  
32 childcare skills.

44  
45 Our multivariate analysis of practices related to neonatal jaundice revealed that mothers who had received  
46 prior education on neonatal jaundice from medical staff were more likely to have good practices related to  
47 jaundice than other mothers. This finding was consistent with a study conducted in Nigeria<sup>[43]</sup> that showed  
48 mothers who obtained knowledge about neonatal jaundice from medical staff were significantly less likely  
49 to self-treat and more likely to seek medical treatment promptly. We also found that mothers with good  
50 knowledge about neonatal jaundice were more likely to have good attitudes and practices; this was  
51 consistent with the ‘knowledge, attitudes practices’ (KAP) model,<sup>[44]</sup> which suggests greater knowledge is  
52 the basis for good attitudes and practices.

## LIMITATIONS

This study had some limitations. One limitation was that when recruiting mothers, we might have motivated them to learn about neonatal jaundice, which would have improved mothers' awareness of neonatal jaundice before the investigation. However, Chinese traditional culture indicates that mothers need to confine themselves for 1 month after giving birth, so they do not leave their homes during this period. This also made it difficult to recruit mothers after discharge from the hospital. To increase the accessibility of the population, this study recruited mothers in advance during the hospitalisation period after delivery. Another limitation was that our research findings are only representative of mothers' KAP, but for some infants, the main caregivers are other people such as grandmothers, sisters or aunts. The findings of this study are not representative of these individuals.

## CONCLUSION

Overall, mothers' knowledge about jaundice was low, especially regarding causes, danger signs and breast milk jaundice. Active information seeking behaviour about neonatal jaundice needs to be improved. Therefore, it is recommended that medical staff incorporate information about the causes, danger signs and breast milk jaundice into neonatal jaundice health education programmes and provide reliable websites for mothers to obtain information about neonatal jaundice. This study also showed that the mother's education level was an important factor that is significantly associated with knowledge about jaundice. In addition, mothers receiving care from a *yuesao* tend to have positive attitudes toward jaundice. Enhancing jaundice-related education programmes targeting mothers with a low education level and no *yuesao* care is important.

**Acknowledgments:** We would like to acknowledge seven neonatologists and my research team for giving feedback to the questionnaire development. Our appreciation also goes to the study participants for generously spending time and providing information in this survey.

**Contributors:** Y.H. and L.C. are joint first authors. Y.H., L.C., and X.J.W. designed the study. Y.H., X.J.W., C.Z., Z.L.G., F.Y., and J.L. collected the data. Y.H., L.C., and X.J.W. analyzed the data. HY drafted the manuscript. W.Z.C., Y.H. and L.C. contributed to the interpretation of the results and critical revision of the manuscript for important intellectual content and approved the final version of the manuscript. All authors have read and approved the final manuscript. W.Z.C., Y.H., and L.C. are the study

**Table 2. Maternal knowledge about neonatal jaundice (N=403)**

Items	True n (%)	False n (%)	Don't know n (%)	Correct rate n (%)
<b>Observation of neonatal jaundice</b>				
When newborns develop jaundice, their skin will turn yellow.	390 (96.8)	4 (1.0)	9 (2.2)	390 (96.8)
When newborns develop jaundice, their face will turn yellow first.	344 (85.4)	12 (3.0)	47 (11.7)	344 (85.4)
When looking for jaundice, check the naked baby in bright and preferably natural light.	365 (90.6)	10 (2.5)	28 (6.9)	365 (90.6)
<b>Classification of neonatal jaundice</b>				
Neonatal jaundice is divided into physiological jaundice and pathological jaundice.	371 (92.1)	3 (0.7)	29 (7.2)	371 (92.1)
<b>Danger signs of neonatal jaundice</b>				
Palms and soles turn yellow, indicating that jaundice is severe.	265 (65.8)	29 (7.2)	109 (27.0)	265 (65.8)
It is an abnormal condition if the jaundice appears within first 24 h.	146 (36.2)	155 (38.5)	102 (25.3)	146 (36.2)
It is an abnormal condition that the jaundice reappears after it has subsided.	149 (37.0)	143 (35.5)	111 (27.5)	149 (37.0)
<b>Complication of neonatal jaundice</b>				
Severe jaundice may lead to brain damage.	325 (80.6)	7 (1.7)	71 (17.6)	325 (80.6)
<b>Cause of neonatal jaundice</b>				
The mother's blood type is O, and the father's blood type is A, B, or AB, which may cause neonatal jaundice.	228 (56.6)	38 (9.4)	137 (34.0)	228 (56.6)
Cranial hematoma may cause neonatal jaundice.	117 (29.0)	39 (9.7)	247 (61.3)	117 (29.0)
Bowel obstruction may cause neonatal jaundice.	281 (69.7)	14 (3.5)	108 (26.8)	281 (69.7)
Broad bean disease (G6PD) may cause jaundice.	163 (40.4)	25 (6.2)	215 (53.3)	163 (40.4)

Breastfeeding may cause jaundice	200 (49.6)	109 (27.0)	94 (23.3)	200 (49.6)
<b>Breast milk jaundice</b>				
Breast milk jaundice is a benign and self-limited condition, and interruption of breast feeding is not recommended as a therapeutic intervention.	149 (37.0)	135 (33.5)	119 (29.5)	149 (37.0)
<b>Diagnosis of neonatal jaundice</b>				
Blood test is the gold standard for diagnosing neonatal jaundice.	138 (34.2)	127 (31.5)	138 (34.2)	138 (34.2)
<b>Treatment of neonatal jaundice</b>				
Phototherapy is a common, effective and safe treatment method for neonatal jaundice.	367 (91.1)	3 (0.7)	33 (8.2)	367 (91.1)

**Table 3. Maternal attitudes towards neonatal jaundice (N=403)**

Items	Strongly disagree n (%)	Disagree n (%)	Not sure n (%)	Agree n (%)	Strongly agree n (%)
I think neonatal jaundice is a common physiological phenomenon and will not cause serious consequences. (-)	80 (19.1)	216 (53.6)	63 (15.6)	39 (9.7)	5 (1.2)
I think that a baby with jaundice, does not need treatment and will self-recover. (-)	151 (38.5)	201 (49.9)	43 (10.7)	6 (1.5)	2 (0.5)
I think it is very important to observe neonatal jaundice after discharged from the hospital.	5 (1.2)	0 (0.0)	6 (1.5)	181 (44.9)	211 (52.4)
I think it is necessary for post-partum visitors to assess jaundice condition.	8 (1.0)	0 (0.0)	8 (2.0)	182 (45.2)	209 (51.9)
I think a baby with suspected jaundice should go to a medical institution or community healthcare centre to measure the bilirubin level	3 (0.7)	5 (1.2)	10 (2.5)	230 (57.1)	155 (37.5)

in a timely manner.

I believe that adequate breastfeeding is good for jaundice. 5 (1.2) 29 (7.2) 84 (20.8) 196 (48.6) 89 (22.1)

I think it is necessary to learn knowledge of neonatal jaundice. 2 (0.5) 0 (0.0) 10 (2.5) 216 (53.6) 175 (43.4)

**Note:** - represents reverse scored items.

**Table 4. Maternal practices regarding neonatal jaundice (N=403)**

Items	Yes n (%)	No n (%)
I took the initiative to seek information about neonatal jaundice.	168 (41.7)	235 (58.3)
After discharge, I checked my infant for jaundice, such as the colour of the skin, sclerae, urine, bowel movements.	387 (96.0)	16 (4.0)
After discharge, I followed the doctor's instructions to take the infant to a medical institution or community healthcare centre to measure the bilirubin level.	376 (93.3)	27 (6.7)
After discharge, I breastfed adequately.	359 (89.1)	44 (10.9)

60STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Reported on page number
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	Page 1: title page
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	Page 2-3
<b>Introduction</b>			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	Page 3-4
Objectives	3	State specific objectives, including any prespecified hypotheses	Page 4
<b>Methods</b>			
Study design	4	Present key elements of study design early in the paper	Page 4
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	Page 4 and Figure 1 data collection progress
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	Page 4
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	Page 6: The levels of knowledge, attitude and practice (for poor, for good)
Data sources/measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	Page 4-6
Bias	9	Describe any efforts to address potential sources of bias	Page 2-3 Strengths and limitations of this study
Study size	10	Explain how the study size was arrived at	NI: Sufficient sample size
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	Page 6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	Page 6
		(b) Describe any methods used to examine subgroups and interactions	Page 6
		(c) Explain how missing data were addressed	Page 5-6 excluded 10 participants' data
		(d) If applicable, describe analytical methods taking account of	NA

		sampling strategy	
		(e) Describe any sensitivity analyses	NA
<b>Results</b>			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	Figure 1 data collection progress
		(b) Give reasons for non-participation at each stage	Figure 1 data collection progress
		(c) Consider use of a flow diagram	Figure 1 data collection progress
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Page 6 and Table 1
		(b) Indicate number of participants with missing data for each variable of interest	NI
Outcome data	15*	Report numbers of outcome events or summary measures	Page 6-7
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Page 7 and Table 5
		(b) Report category boundaries when continuous variables were categorized	NI
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	NA
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	NA
<b>Discussion</b>			
Key results	18	Summarise key results with reference to study objectives	Page 7-9
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	Page 2-3
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	Page 10
Generalisability	21	Discuss the generalisability (external validity) of the study results	Page 7-9
<b>Other information</b>			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	Page 10-11

## ABSTRACT

**Objective:** This study aimed to assess knowledge, attitudes and practices related to neonatal jaundice among mothers in Shenzhen, China and analyse associated factors.

**Design:** A cross-sectional study.

**Setting:** This study was conducted in Shenzhen Hospital, Southern Medical University, a university-affiliated, tertiary level-A, public hospital in China. On average, 4000 mothers are discharged from this hospital after childbirth each year, most of whom can access a mobile phone and the Internet.

**Participants:** Participants were 403 mothers discharged from the study hospital within 48 to 72 hours after vaginal delivery or 96 to 120 hours after caesarean delivery between April and June 2021. Participants were recruited using convenience sampling.

**Primary outcome:** Mothers' knowledge, attitudes and practices related to neonatal jaundice, modelled using binary logistic regression.

**Secondary outcomes:** Factors associated with mothers' knowledge, attitudes and practices related to neonatal jaundice.

**Results:** The questionnaire was reliable (Cronbach's alpha=0.802) and valid (scale-level content validity index=0.958). The valid response rate was 96.4%. Only 46.4% of participating mothers had good knowledge about neonatal jaundice and 41.7% indicated they would seek information about neonatal jaundice. A binary logistic regression analysis showed good knowledge about jaundice was associated with a high education level (i.e., master's degree or above; odds ratio [OR]=5.977, 95% confidence interval [CI]: 1.994~17.916,  $P=0.001$ ), prior education on neonatal jaundice ( $OR=3.617$ , 95%CI: 1.637~7.990,  $P=0.001$ ), and male babies ( $OR=1.714$ , 95%CI: 1.122~2.167,  $P=0.013$ ). A positive attitude toward jaundice was associated with being cared for by a 'yuesao' (maternity matron specialised in caring for mothers and newborns) ( $OR=1.969$ , 95%CI: 1.264~3.066,  $P=0.003$ ) and good knowledge about jaundice ( $OR=1.804$ , 95%CI: 1.194~2.726,  $P=0.005$ ). Finally, good practices related to neonatal jaundice were associated with prior education on neonatal jaundice ( $OR=2.260$ , 95%CI: 1.105~4.625,  $P=0.026$ ) and good knowledge about jaundice ( $OR=3.112$ , 95%CI: 2.040~4.749,  $P<0.001$ ).

**Conclusion:** Many mothers have poor knowledge about jaundice, especially regarding causes, danger signs and breast milk jaundice. Maternal information seeking behaviour about neonatal jaundice needs to be improved. Medical staff should incorporate information about the causes/danger signs of jaundice and breast milk jaundice in maternal health education. It is also necessary to strengthen health education for mothers, especially those with low education and no yuesao, and provide reliable websites where mothers can obtain information about neonatal jaundice.

### Strengths and limitations of this study

- A strength of this study was that participants were mothers with healthy infants who had been discharged from the birth hospital; these mothers may be more likely to ignore the problem of jaundice.
- The investigation time was the peak period of jaundice occurrence, which aimed to avoid recall bias.
- Recruiting mothers and then surveying them at a later time may have prompted mothers to search for information about jaundice.
- This study focused on new mothers and did not include significant others who may have roles in care of the newborn (e.g. grandmothers, sisters or aunts).

### INTRODUCTION

Neonatal jaundice, also known as neonatal hyperbilirubinemia, refers to yellow staining of the skin or other organs caused by the accumulation of bilirubin in the body.<sup>[1]</sup> It is a common clinical problem in the neonatal period, and approximately 50%~60% of full-term infants and 80% of premature infants develop jaundice within 1 week after birth.<sup>[2]</sup> In many infants, neonatal jaundice is a benign condition. However, severe hyperbilirubinemia may cause acute bilirubin encephalopathy (ABE) or kernicterus, which may progress to nerve deafness, choreoathetoid cerebral palsy, intellectual disability and even death.<sup>[3-4]</sup> A report from China showed that from January to December 2009, 348 cases of kernicterus were recorded in 33 hospitals.<sup>[5]</sup> In addition, a worldwide survey reported that at least 480,700 newborns develop severe hyperbilirubinemia each year, with the risk for kernicterus being 13% (n=75,400) and that for death being 24% (n=114,100).<sup>[6]</sup> Therefore, neonatal jaundice is a serious threat to the life and health of newborns, and the associated high rates of disability and mortality place heavy burdens on society and families.

Early detection and timely treatment of neonatal jaundice are key strategies to prevent ABE and kernicterus. However, neonatal jaundice generally peaks on the 5th~7th day after birth,<sup>[1]</sup> at which time most healthy full-term infants have been discharged from hospital. Therefore, most neonatal jaundice occurs at home. As the main caregivers of newborns after discharge from hospital, mothers are often the first to observe jaundice, its progression, and early signs of ABE and kernicterus. They are central to achieving favourable outcomes for management of neonatal jaundice. Wennberg<sup>[7]</sup> et al reported that providing mothers with detailed information about neonatal jaundice and its risks was associated with a reduction in the incidence of ABE in Nigeria. The Stop Kernicterus in Nigeria (SKIN) consortium<sup>[8]</sup> demonstrated that a delay in seeking care, regardless of birth site, was a major contributor to ABE and kernicterus and proposed that maternal education on neonatal jaundice should be targeted as an intervention strategy. The clinical practice guidelines for neonatal jaundice from the National Institute for Health and Care Excellence<sup>[9]</sup> and American Academy of Pediatrics Subcommittee<sup>[2]</sup> also recommend

1 parents and caregivers are educated about neonatal jaundice, especially on how to check their baby for jaundice and  
2 what to do when jaundice is suspected. These guidelines suggest that maternal jaundice instruction be given high  
3 priority among the myriad topics. However, effective instruction starts with meaningful engagement between  
4 hospital staff and mothers.<sup>[10]</sup> Hospital staff therefore need to clarify what mothers know about jaundice and their  
5 current attitudes and practices, which will allow health education programmes to target identified gaps. Although  
6 similar investigations have been done in other countries or regions including Ghana,<sup>[11]</sup> Accra,<sup>[12]</sup> and Egypt,<sup>[13]</sup> no  
7 evaluation tools or reports related to maternal knowledge, attitudes and practices about neonatal jaundice are  
8 available in China.

9 Therefore, this study designed a questionnaire to assess knowledge, attitudes and practices related to neonatal  
10 jaundice among mothers in Shenzhen, China. The information obtained maybe used to assist healthcare providers  
11 in designing educational programmes to improve awareness about neonatal jaundice among mothers, which will  
12 ultimately help to prevent disability and deaths among newborns.

## 13 **METHODS**

### 14 **Study setting and design**

15 We conducted an anonymous, self-administered, cross-sectional survey involving 403 mothers in Shenzhen, China  
16 from April to June 2021. Participants were recruited using convenience sampling.

### 17 **Study population**

18 The target population was mothers who gave birth at Shenzhen Hospital, Southern Medical University, China from  
19 April to June 2021.

### 20 **Inclusion and exclusion criteria**

21 Mothers were eligible for this study if they were discharged from the hospital without serious illness after  
22 childbirth and had access to a mobile phone and the Internet. Mothers were excluded if they were not the main  
23 caregiver of their newborn after being discharged from hospital or could not complete the questionnaire by  
24 themselves. Moreover, we excluded mothers whose newborns were admitted to the neonatal intensive care unit for  
25 treatment or that died after birth.

### 26 **Ethical considerations**

27 Ethical clearance was obtained from the Ethical Review Committee of Shenzhen Hospital of Southern Medical  
28 University (approval number: NYSZYEC20210004). Data were collected from each participant after they  
29 received a clear explanation of the purpose and importance of this study and provided informed consent.  
30 Participating mothers were informed that participation was voluntary, and they could withdraw from the study at  
31 any time or refuse to answer any question. They were also informed they could ask for clarification about any

1 aspect of the study and that the study would not cause harm. Participants did not receive any monetary incentive to  
2 participate in this study. All personal information was de-identified and kept securely, and every effort was made to  
3 maintain participants' confidentiality. Furthermore, after the investigation, each mother was informed via mobile  
4 phone text messages about seeking healthcare from a nearby clinic immediately if any signs of jaundice were  
5 identified.  
6  
7  
8  
9

### 10 **Data collection tools**

11 Data were collected using a questionnaire that covered baseline characteristics, knowledge, attitudes and practices  
12 regarding neonatal jaundice. These items were developed with reference to: 1) an established guideline on neonatal  
13 jaundice,<sup>[9]</sup> 2) an integrative review,<sup>[14]</sup> and 3) three services for investigating maternal knowledge, attitude and  
14 behaviour regarding neonatal jaundice.<sup>[13, 15, 16]</sup> We also consulted seven neonatologists and discussed the items  
15 among the research team. Following the review by the expert panel, nine mothers whose babies had experienced  
16 neonatal jaundice were conveniently recruited to provide input on the importance and clarity of the questionnaire  
17 items. Mothers were asked to suggest alternative wording for existing items and identify items that required  
18 deletion and addition as necessary. Some items were modified based on this review. For example, we modified  
19 'Have you ever learned about neonatal jaundice' to 'Prior health education on neonatal jaundice', 'G6PD  
20 deficiency' to 'Broad bean disease', and 'Serum total bilirubin is the gold standard for diagnosing neonatal  
21 jaundice' to 'Blood test is the gold standard for diagnosing neonatal jaundice'. No items were identified for  
22 deletion or addition. The draft questionnaire was then pretested with 20 mothers who were conveniently selected  
23 from the same hospital based on the study inclusion criteria and exclusion criteria. The final version of the  
24 questionnaire included 27 items. Sixteen items evaluated knowledge (categorical responses: 'true', 'false', 'do not  
25 know'), seven items assessed attitude (categorical responses: 'strongly agree', 'agree', 'not sure', 'disagree',  
26 'strongly disagree'), and four items covered practices (yes/no responses).

41  
42  
43

### 44 **Validity and reliability**

45 The content validity of the questionnaire was appraised quantitatively by sending the final version of the  
46 questionnaire to a group of experts including seven specialists in the field of neonatology. Based on the experts'  
47 feedback about relevance, the instrument's scale-level content validity index was calculated as 0.958, which was  
48 higher than the value of 0.8 that indicates adequate validity.<sup>[17]</sup>  
49

50 Cronbach's alpha<sup>[18]</sup> was used to check the reliability of the questionnaire, which is the most common measure of  
51 internal consistency. In this study, the Cronbach's alphas were 0.802 for the whole questionnaire, 0.789 for the  
52 knowledge dimension, 0.721 for the attitude dimension and 0.414 for the practice dimension. The Cronbach's  
53 alphas for the knowledge and attitude dimensions were higher than 0.7, and were within the acceptable  
54  
55  
56  
57  
58  
59  
60

1 recommended range. However, that for practice (0.414) was below 0.7.<sup>[19]</sup> The small number of items (four items)  
2 on that dimension may explain the low alpha estimate. To avoid the impact of a small number of items,  
3 Cronbach<sup>[20]</sup> proposed the mean inter-item correlation ( $\rho$ ) in 1951 to estimate the internal consistency of  
4 dimensions with a small number of items. Generally, a mean inter-item correlation ( $\rho$ ) between 0.15 and 0.20  
5 indicates acceptable internal consistency. <sup>[21]</sup> In this study, the mean inter-item correlation was 0.15 for the practice  
6 dimension, which was within the acceptable range.

### 12 **Data collection procedure**

13  
14 On the day each mother was discharged after delivery, the investigator informed them of the purpose, duration and  
15 method of this study, and obtained their phone number. About 5 days after discharge from hospital, the investigator  
16 sent the questionnaire link, which was developed using the 'Question star' platform, to participating mothers via  
17 mobile phone and then called the participant to complete the questionnaire on the same day. In total, 413  
18 questionnaires were completed. We excluded 10 participants: three did not complete the questionnaire, three wrote  
19 their names instead of their age, two had missing data for age, one wrote her age as '240' and one participant chose  
20 the first option for each question. This left 403 valid questionnaires for analysis, giving an effective recovery rate of  
21 96.4%. Detailed data collection procedures are presented in supplementary figure 1.

27  
28  
29

### 30 **Data processing and analysis**

31  
32 We used SPSS version 25.0 (IBM Corp., Armonk, NY) for all data analyses. Descriptive statistics were calculated  
33 for baseline characteristics and categorical variables using simple frequencies and percentages. The main outcome  
34 variables were knowledge, attitudes and practices. The knowledge score for each participant was determined by  
35 allotting a score of '1' to correct responses and '0' (zero) to incorrect and 'do not know' responses. Therefore, the  
36 maximum obtainable knowledge score was 16. A knowledge score  $\leq 10$  was considered poor knowledge, and scores  
37  $> 10$  represented good knowledge.<sup>[22]</sup> The attitude scores were obtained by assigning points to responses on the  
38 5-point Likert scale (1 point for 'strongly disagree' to 5 points for 'strongly agree'). The maximum obtainable  
39 attitude score was 35 points. An attitude score  $\leq 28$  was considered a poor attitude and scores  $> 29$  were categorised  
40 as good attitudes.<sup>[22]</sup> Similarly, the practice score for each participant was determined by allotting a score of '1' to  
41 correct responses and '0' (zero) to incorrect responses. This gave a maximum obtainable practice score of 4. Those  
42 with a practice score  $< 4$  were regarded as having poor practice, whereas a score of 4 was considered to reflect good  
43 practice.<sup>[22]</sup> Finally, the levels of knowledge, attitude and practice were coded as 0 for poor, 1 for good.<sup>[22]</sup>

52  
53  
54  
55  
56  
57  
58  
59  
60  
Chi-square tests (bivariable analyses) were used to determine the associations between the baseline and outcome  
variables. All variables with  $P < 0.05$  in the bivariable analysis were included in the binary logistic regression  
(multivariable analysis) to determine the associations between dependent (knowledge, attitudes and practices) and

independent (baseline characteristics) variables. In consideration of having yuesao or not is related to salary range and education, which are supposed to affect attitude and knowledge towards neonatal jaundice. Thus, another comparison had been done to differentiate those without yuesao and with yuesao in correlation to education, salary in terms of attitude and knowledge. Statistical significance was represented by  $P < 0.05$  at a 95% confidence level.

### Patient and public involvement

Before the formal survey, the researchers interviewed 20 mothers to determine the readability of the questionnaire, the time required and the best way to conduct the investigation.

## RESULTS

### Participants' baseline characteristics

Of the 403 mothers included in our analyses, a majority were aged 28~32 years (48.9%) and 75.7% had a spontaneous vaginal delivery. Most mothers (80.6%) had received prior health education about jaundice from health workers on the day of normal discharge from the delivery hospital (48 to 72 hours after vaginal delivery or 96 to 120 hours after caesarean delivery). Among the 403 participating mothers, 113 (28%) reported their current child was admitted to the hospital for treatment due to jaundice after discharge, and 56 (13.9%) had a previous child with a history of neonatal jaundice. Participants' baseline characteristics are presented in Table 1.

**Note:** <sup>1</sup>Weight: low weight <2500 g; normal weight 2500–4000 g; high weight >4000 g. <sup>2</sup>Cranial haematoma: haematoma caused by rupture and bleeding of subperiosteal vessels in the parieto-occipital region due to birth injury. <sup>3</sup>yuesao: maternity matron specialised in caring for mothers and newborns.

### Mothers' knowledge of neonatal jaundice

We found that 45.4% of participating mothers had good knowledge regarding neonatal jaundice. The rates of correct answers to the knowledge questions ranged from 29% to 96.8%. Questions that showed low rates of correct answers were: 'Cranial haematoma may cause neonatal jaundice' (29%), 'Blood test is the gold standard for diagnosing neonatal jaundice' (34.2%), 'It is abnormal for jaundice to appear within 24 hours after birth' (36.2%), 'It is abnormal for jaundice to reappear after it subsides' (37%), and 'Breast milk jaundice is a benign and self-limited condition, and interruption of breast feeding is not recommended as a therapeutic intervention' (37%).

Table 2 presents scores for knowledge about neonatal jaundice among participating mothers.

53 **Mothers' attitudes towards neonatal jaundice**

54 The results revealed that 42.2% of participating mothers had poor attitudes towards neonatal jaundice. Over half of  
55 the participants strongly agreed that post-discharge observation was necessary and post-partum visits were needed  
56 to measure the bilirubin level (52.4% and 51.9%, respectively). However, some mothers believed that neonatal  
57  
58  
59  
60

jaundice was a common physiological phenomenon that would not cause serious consequences (10.9%), and 29.2% lacked understanding that adequate feeding was conducive to resolving jaundice. Mothers' attitudes towards neonatal jaundice are presented in Table 3.

**Table 3. Maternal attitudes towards neonatal jaundice (N=403)**

Items	Strongly disagree n (%)	Disagree n (%)	Not sure n (%)	Agree n (%)	Strongly agree n (%)
I think neonatal jaundice is a common physiological phenomenon and will not cause serious consequences. (-)	80 (19.1)	216 (53.6)	63 (15.6)	39 (9.7)	5 (1.2)
I think that a baby with jaundice, does not need treatment and will self-recover. (-)	151 (38.5)	201 (49.9)	43 (10.7)	6 (1.5)	2 (0.5)
I think it is very important to observe neonatal jaundice after discharged from the hospital.	5 (1.2)	0 (0.0)	6 (1.5)	181 (44.9)	211 (52.4)
I think it is necessary for post-partum visitors to assess jaundice condition.	8 (1.0)	0 (0.0)	8 (2.0)	182 (45.2)	209 (51.9)
I think a baby with suspected jaundice should go to a medical institution or community healthcare centre to measure the bilirubin level in a timely manner.	3 (0.7)	5 (1.2)	10 (2.5)	230 (57.1)	155 (37.5)
I believe that adequate breastfeeding is good for jaundice.	5 (1.2)	29 (7.2)	84 (20.8)	196 (48.6)	89 (22.1)
I think it is necessary to learn knowledge of neonatal jaundice.	2 (0.5)	0 (0.0)	10 (2.5)	216 (53.6)	175 (43.4)

**Note:** - represents reverse scored items.

#### **Mothers' practices regarding neonatal jaundice**

In general, 53.1% of mothers had good practices regarding neonatal jaundice, and 96% checked their baby for jaundice after discharge. However, only 41.9% indicated they would take the initiative to learn about neonatal jaundice after discharge. Mothers' practices regarding jaundice are shown in Table 4.

**Table 4. Maternal practices regarding neonatal jaundice (N=403)**

Items	Yes n (%)	No n (%)
I took the initiative to seek information about neonatal jaundice.	168 (41.7)	235 (58.3)
After discharge, I checked my infant for jaundice, such as the colour of the skin, sclerae, urine, bowel movements.	387 (96.0)	16 (4.0)
After discharge, I followed the doctor's instructions to take the infant to a medical institution or community healthcare centre to measure the bilirubin level.	376 (93.3)	27 (6.7)
After discharge, I breastfed adequately.	359 (89.1)	44 (10.9)

### Factors associated with knowledge, attitudes and practices related to neonatal jaundice among mothers

The binary logistic regression analysis revealed that good knowledge about jaundice was associated with a high level of education (master's degree or above; odds ratio [OR]=5.977, 95% confidence interval [CI]: 1.994~17.916,  $P=0.001$ ), receiving prior health education on neonatal jaundice ( $OR=3.617$ , 95%CI: 1.637~7.990,  $P=0.001$ ), and male babies ( $OR=1.714$ , 95%CI: 1.122~2.167,  $P=0.013$ ). A positive attitude towards jaundice was associated with being cared for by a 'yuesao' (matron specialised in maternal and newborn care) ( $OR=1.969$ , 95%CI: 1.264~3.066,  $P=0.003$ ) and good knowledge about jaundice ( $OR=1.804$ , 95%CI: 1.194~2.726,  $P=0.005$ ). Finally, good practices related to jaundice were associated with prior health education on neonatal jaundice ( $OR=2.260$ , 95%CI: 1.105~4.625,  $P=0.026$ ) and good knowledge about jaundice ( $OR=3.112$ , 95%CI: 2.040~4.749,  $P<0.001$ ). The results of chi-square tests (bivariable analyses) for maternal knowledge, attitudes and practices related to neonatal jaundice are shown in supplementary table 1. Factors associated with knowledge, attitudes and practices related to neonatal jaundice among mothers are shown in Table 5. Binary logistic regression analysis of maternal knowledge, attitudes and practices related to neonatal jaundice for mothers with and without yuesao are shown in supplementary table 2 and supplementary table 3.

## DISCUSSION

In this study, 45.4% of mothers had good knowledge about neonatal jaundice. This knowledge level was better than that reported in other countries such as Nepal<sup>[23]</sup> (22%), Egypt <sup>[24]</sup> (30%) and Karbala city, Iraq<sup>[25]</sup> (34%). This may be attributed to the high proportion (83.1%) of our respondents who had graduated from university. Our study also found that education level was significantly associated with knowledge about neonatal jaundice, which was consistent with the results of an earlier review.<sup>[26]</sup> Due to differences in scoring algorithms or items investigating attitudes and practices<sup>[23-25]</sup>, it was difficult to compare attitudes and behaviours reported in our study with those from other countries.

The majority (80.6%) of participants in this study had received prior health education on neonatal jaundice, which suggested that their knowledge about neonatal jaundice would be high. However, this study found that many mothers had poor knowledge regarding neonatal jaundice, with only 45.5% of participating mothers had good knowledge about neonatal jaundice. This large gap may be attributable to the gap of nearly a week between the time they received health education and the time of our investigation; some mothers might have forgotten the content of the health education. In addition, medical staff only provided post-discharge monitoring and follow-up instruction and did not include neonatal jaundice knowledge related to the questionnaire when conducting health education. Another factor that might have contributed to the comparative ineffectiveness of postnatal instruction was that the unique environment was absent that mothers received health education about jaundice from health workers in a single setting, which combined a lecture, demonstration and interactive discussion, as there is generally a rush to discharge mothers from birthing centres.

The present study reported that many mothers had poor knowledge regarding the causes and danger signs of jaundice. Relatively few mothers provided correct answers to some items; for example, 'Cranial haematoma may cause neonatal jaundice' (29%), 'Blood test is the gold standard for diagnosing neonatal jaundice' (34.2%), 'It is abnormal for jaundice to appear within 24 hours after birth' (36.2%), and 'It is abnormal for jaundice to reappear after it subsides' (37%). Poor knowledge about the causes and danger signs of jaundice may mean mothers turn to traditional treatments, which results in delays in seeking medical attention for neonatal jaundice, thereby contributing to the development of ABE and kernicterus.<sup>[11]</sup> Therefore, it is recommended that medical staff incorporate information about the causes

1  
2  
3  
4  
5 and danger signs of jaundice into neonatal jaundice health education programmes. For breast milk  
6 jaundice, this involves monitoring the jaundice without changing in the infant's breastfeeding,<sup>[27]</sup>  
7 however, 73% of mothers in this study did not know that breast milk jaundice is generally a benign  
8 condition, where interruption of breast feeding is not recommended as a therapeutic intervention. Having  
9 poor knowledge of breast milk jaundice may mean mothers discontinue breastfeeding after jaundice occurs.  
10 However brief, such discontinuation may jeopardise an infant's ability to return to exclusive breastfeeding,  
11 which is unnecessarily harmful to the infant and traumatic for mothers.<sup>[28]</sup> This means mothers of affected  
12 infants should be educated about breast milk jaundice and informed that breastfeeding should be  
13 interrupted in rare instances (i.e. if the neonate displays signs of ABE). In addition, the incidence of G6PD  
14 deficiency is high in Shenzhen.<sup>[29-30]</sup> Traditional Chinese medicine is widely used in China to prevent or  
15 treat neonatal jaundice.<sup>[31-32]</sup> However, neonates with G6PD deficiency that use such remedies may have  
16 severe jaundice.<sup>[33]</sup> Our findings suggested that most mothers (59.5%) did not know the G6PD deficiency  
17 may cause jaundice. Therefore, mothers whose neonates have G6PD deficiency should be educated about  
18 avoiding using traditional Chinese medicine to treat or prevent neonatal jaundice.

27  
28  
29  
30  
31  
32 Importantly, our study highlighted that maternal information seeking behaviour related to neonatal  
33 jaundice needs to be improved. Only 41.7% of mothers in this study indicated they took the initiative to  
34 seek information about neonatal jaundice. This poor practice could be because physical and psychological  
35 changes in the postpartum period mean mothers' energy is limited. However, it could also be attributable  
36 to health literacy, which has an impact on people's health information seeking behaviour.<sup>[34]</sup> A previous  
37 study<sup>[34]</sup> reported that the lower the parents' health literacy, the less likely they were to take the initiative  
38 to obtain information about their child's health. Actively understanding relevant knowledge will help to  
39 improve maternal awareness of neonatal jaundice, which will be conducive to managing neonatal jaundice  
40 after discharge from hospital. In addition, with the popularisation of the Internet and smart phones, more  
41 parents are using these ways to access parenting knowledge. However, they complain that they face major  
42 challenges in identifying whether the information is reliable.<sup>[35-36]</sup> Therefore, it is recommended that when  
43 providing education about neonatal jaundice, medical staff also provide mothers with some reliable  
44 websites to facilitate the active information seeking about neonatal jaundice.

57 Our multivariate analysis revealed that mothers who had a male infant were more likely be  
58  
59  
60

1  
2  
3  
4  
5 knowledgeable about neonatal jaundice compared with mothers who had a female infant. Health  
6 workers generally perform routine jaundice evaluation during birth hospitalisation, and male sex is a  
7 risk factor for neonatal jaundice.<sup>[37]</sup> We speculated that mothers who gave birth to male infants had more  
8 opportunities to receive information about neonatal jaundice. A high education level was determinant of  
9 knowledge about neonatal jaundice. This finding was consistent with the results of a study from Egypt<sup>[13]</sup>  
10 that found mothers who were university graduates had the highest knowledge scores. This suggested it is  
11 necessary for medical staff to provide information about jaundice to mothers with lower education levels.  
12 Interestingly, for the mothers without yuesao, the binary logistic regression analysis revealed that good  
13 knowledge about jaundice was associated with receiving prior health education on neonatal jaundice from  
14 medical staff. However, for the mothers with yuesao, no statistically significant association was detected  
15 between prior health education on neonatal jaundice and knowledge towards jaundice. This may be  
16 because the yuesao offers a valuable resource for jaundice counselling. Chinese tradition dictates that  
17 new mothers stay home and rest for a 'confinement period' of about 1 month (28 to 42 days) after  
18 giving birth, which is thought to facilitate recovery. Previous studies reported that being cared for  
19 by a yuesao during this stage can help improve the health of mothers and babies,<sup>[38-39]</sup> reduce  
20 postpartum depression,<sup>[40-41]</sup> and facilitate breastfeeding.<sup>[42]</sup> Therefore, hiring a yuesao to prepare  
21 post-partum foods and help with household and childcare tasks has become increasingly popular in  
22 many urban families. However, not everyone can afford their services. This suggested it is necessary for  
23 hospitals to give mothers pamphlet on neonatal jaundice in which informations on recommended websites  
24 to seek further information can be obtained. This will help mothers especially those who cannot afford a  
25 yuesao.

43  
44  
45  
46 Our multivariate analysis of practices related to neonatal jaundice revealed that mothers who had received  
47 prior education on neonatal jaundice from medical staffs were more likely to have good practices related to  
48 jaundice than other mothers. This finding was consistent with a study conducted in Nigeria<sup>[43]</sup> that showed  
49 mothers who obtained knowledge about neonatal jaundice from medical staff were significantly less likely  
50 to self-treat and more likely to seek medical treatment promptly. We also found that mothers with good  
51 knowledge about neonatal jaundice were more likely to have good attitudes and practices; this was  
52 consistent with the 'knowledge, attitudes practices' (KAP) model,<sup>[44]</sup> which suggests greater knowledge is  
53

5 the basis for good attitudes and practices.

## 6 7 **LIMITATIONS**

8  
9 This study had some limitations. One limitation was that when recruiting mothers, we might have  
10 motivated them to learn about neonatal jaundice, which would have improved mothers' awareness of  
11 neonatal jaundice before the investigation. However, Chinese traditional culture indicates that mothers  
12 need to confine themselves for 1 month after giving birth, so they do not leave their homes during this  
13 period. This also made it difficult to recruit mothers after discharge from the hospital. To increase the  
14 accessibility of the population, this study recruited mothers in advance during the hospitalisation period  
15 after delivery. Another limitation was that our research findings are only representative of mothers' KAP,  
16 but for some infants, the main caregivers are other people such as grandmothers, sisters or aunts. The  
17 findings of this study are not representative of these individuals.

## 18 19 20 21 22 23 24 25 26 **CONCLUSION**

27  
28 Overall, mothers' knowledge about jaundice was low, especially regarding causes, danger signs and breast  
29 milk jaundice. Active information seeking behaviour about neonatal jaundice needs to be improved.  
30 Therefore, it is recommended that medical staff incorporate information about the causes, danger signs and  
31 breast milk jaundice into neonatal jaundice health education programmes and provide reliable websites for  
32 mothers to obtain information about neonatal jaundice. This study also showed that the mother's education  
33 level was an important factor that is significantly associated with knowledge about jaundice. In addition,  
34 mothers receiving care from a *yuesao* tend to have positive attitudes toward jaundice. Enhancing  
35 jaundice-related education programmes targeting mothers with a low education level and no *yuesao* care is  
36 important.

STROBE Statement—Checklist of items that should be included in reports of *cross-sectional studies*

	Item No	Recommendation	Reported on page number
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	Page 1: title page
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	Page 2-3
<b>Introduction</b>			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	Page 3-4
Objectives	3	State specific objectives, including any prespecified hypotheses	Page 4
<b>Methods</b>			
Study design	4	Present key elements of study design early in the paper	Page 4
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	Page 4 and Supplementary figure 1 data collection progress
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	Page 4
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	Page 6: The levels of knowledge, attitude and practice (for poor, for good)
Data sources/measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	Page 4-6
Bias	9	Describe any efforts to address potential sources of bias	Page 2-3 Strengths and limitations of this study
Study size	10	Explain how the study size was arrived at	NI: Sufficient sample size
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	Page 6
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	Page 6
		(b) Describe any methods used to examine subgroups and interactions	Page 6
		(c) Explain how missing data were addressed	Page 5-6 excluded 10 participants' data

		(d) If applicable, describe analytical methods taking account of sampling strategy	NA
		(e) Describe any sensitivity analyses	NA
<b>Results</b>			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	Supplementary figure 1 data collection progress
		(b) Give reasons for non-participation at each stage	Supplementary figure 1 data collection progress
		(c) Consider use of a flow diagram	Supplementary figure 1 data collection progress
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Page 7 and Table 1
		(b) Indicate number of participants with missing data for each variable of interest	NI
Outcome data	15*	Report numbers of outcome events or summary measures	Page 6-7
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Page 12 and Table 5
		(b) Report category boundaries when continuous variables were categorized	NI
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	NA
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	NA
<b>Discussion</b>			
Key results	18	Summarise key results with reference to study objectives	Page 15-17
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	Page 18
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	Page 18
Generalisability	21	Discuss the generalisability (external validity) of the study results	Page 18
<b>Other information</b>			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	Page 18-19

**Note:** NI, Not included ; NA, Not available
